This documentation is far from complete. It may have many grammatical (and contextual) errors. Also, several parts are written in Japanese only.
Part I
User’s manual

1 Introduction

The LuaTeX-ja package is a macro package for typesetting high-quality Japanese documents when using LuaTeX.

1.1 Backgrounds

Traditionally, ASCII \pdfTeX, an extension of \TeX, and its derivatives are used to typeset Japanese documents in \TeX. \pdfTeX is an engine extension of \TeX: so it can produce high-quality Japanese documents without using very complicated macros. But this point is a mixed blessing: \pdfTeX is left behind from other extensions of \TeX, especially \eTaTeX and pdf\TeX, and from changes about Japanese processing in computers (e.g., the UTF-8 encoding).

Recently extensions of \pdfTeX, namely up\pdfTeX (Unicode-implementation of \pdfTeX) and \eTa\pdfTeX (merging of \pdfTeX and \eTa\TeX extension), have developed to fill those gaps to some extent, but gaps still exist.

However, the appearance of Lua\TeX changed the whole situation. With using Lua "callbacks", users can customize the internal processing of Lua\TeX. So there is no need to modify sources of engines to support Japanese typesetting: to do this, we only have to write Lua scripts for appropriate callbacks.

1.2 Major changes from \pdfTeX

The LuaTeX-ja package is under much influence of \pdfTeX engine. The initial target of development was to implement features of \pdfTeX. However, implementing all feature of \pdfTeX is impossible, since all process of LuaTeX-ja must be implemented only by Lua and \TeX macros. Hence LuaTeX-ja is not a just porting of \pdfTeX; unnatural specifications/behaviors of \pdfTeX were not adopted.

The followings are major changes from \pdfTeX. For more detailed information, see Part III or other sections of this manual.

- **Command names**  \pdfTeX adds several primitives, such as \kanjiskip, \prebreakpenalty, and \ifydir. They can be used as follows:

  \kanjiskip=10pt \dimen0=kanjiskip
  \tbaselineshift=0.1zw
  \dimen0=tbaselineshift
  \prebreakpenalty`ぁ=100
  \ifydir ... \fi

  However, we cannot use them under Lua\TeX-ja. Instead of them, we have to write as the following.

  \ltjsetparameter{kanjiskip=10pt} \dimen0=\ltjgetparameter{kanjiskip}
  \ltjsetparameter{tbaselineshift=0.1\zw}
  \dimen0=\ltjgetparameter{tbaselineshift}
  \ltjsetparameter{prebreakpenalty={`ぁ,100}}
  \ifnum\ltjgetparameter{direction}=4 ... \fi

  Note that \pdfTeX adds new two useful units, namely zw and zh. As shown above, they are changed to \zw and \zh respectively in Lua\TeX-ja.

- **Linebreak after a Japanese character**  In \pdfTeX, a line break after Japanese character is ignored (and doesn’t yield a space), since line breaks (in source files) are permitted almost everywhere in Japanese texts. However, Lua\TeX-ja doesn’t have this feature completely, because of a specification of Lua\TeX. For the detail, see Section 13.

\[\text{Lua\TeX-ja 20200127.0 introduces } \ltj@zw \text{ and } \ltj@zh, \text{ which are copy of } \zw \text{ and } \zh.\]
Spaces related to Japanese characters  The insertion process of glues/kerns between two Japanese characters and between a Japanese character and other characters (we refer glues/kerns of both kinds as JAglue) is rewritten from scratch.

- As LuaTeX’s internal ligature handling is node-based (e.g., ofICE doesn’t prevent ligatures), the insertion process of JAglue is now node-based.
- Furthermore, nodes between two characters which have no effects in line break (e.g., \special node) and kerns from italic correction are ignored in the insertion process.
- Caution: due to above two points, many methods which did for the dividing the process of the insertion of JAglue in \TeX are not effective anymore. In concrete terms, the following two methods are not effective anymore:
  ちょ{}っと ちょ/っと
  If you want to do so, please put an empty horizontal box (hbox) between it instead:
  ちょ\hbox{}っと
- In the process, two Japanese fonts which only differ in their “real” fonts are identified.

Directions  From version 20150420.0, LuaTeX-ja supports vertical writing. We implement this feature by using callbacks of LuaTeX; so it must not be confused with \Omega-style direction support of LuaTeX itself. Due to implementation, the dimension returned by \wd, \ht, or \dp depends on the content of the register only. This is major difference with \TeX.

\discretionary  Japanese characters in discretionary break (\discretionary) is not supported.

Greek and Cyrillic letters, and ISO 8859-1 symbols  By default, LuaTeX-ja uses Japanese fonts to typeset Greek and Cyrillic letters, To change this behavior, put \ltjsetparameter{jacharrange={-2,-3}} in the preamble. For the detailed description, see Subsection 4.1.

  From version 20150906.0, characters which belongs both ISO 8859-1 and JIS X 0208, such as ¶ and §, are now typeset in alphabetic fonts.

1.3 Notations

In this document, the following terms and notations are used:

- Characters are classified into following two types. Note that the classification can be customized by a user (see Subsection 4.1).
  - JAchar: standing for characters which is used in Japanese typesetting, such as Hira-gana, Katakana, Kanji, and other Japanese punctuation marks.
  - ALchar: standing for all other characters like latin alphabets.

We say alphabetic fonts for fonts used in ALchar, and Japanese fonts for fonts used in JAchar.

- A word in a sans-serif font with underline (like \text{prebreakpenalty}) means an internal parameter for Japanese typesetting, and it is used as a key in \ltjsetparameter command.

- A word in a sens-serif font without underline (like fontspec) means a package or a class of \TeX.

- In this document, natural numbers start from zero. \omega denotes the set of all natural numbers which can be used in \TeX.
1.4 About the project

■ Project Wiki  Project Wiki is under construction.

- [https://osdn.jp/projects/luatex-ja/wiki/FrontPage%28en%29](https://osdn.jp/projects/luatex-ja/wiki/FrontPage%28en%29) (English)

This project is hosted by OSDN.

2 Getting Started

2.1 Installation

The following packages are needed for the Lua\TeX-ja package.

- Lua\TeX 1.10.0 (or later)
- recent luaotfload (v3.1 or later recommended)
- adobemapping (Adobe cmap and pdfmapping files)
- \texttt{\LaTeX} 2020-02-02 patch level 5 or later (if you want to use Lua\TeX-ja with \texttt{\LaTeX} \texttt{\varepsilon})
- etoolbox, everysel (if you want to use Lua\TeX-ja with \texttt{\LaTeX} \texttt{\varepsilon})
- \texttt{ltcems}, \texttt{pdftecmath}, \texttt{filehook}, \texttt{atbegshi}
- \texttt{fontspec} v2.7c (or later)
- Harano Aji fonts (https://github.com/trueroad/HaranoAjiFonts)
  More specifically, HaranoAjiMincho-Regular and HaranoAjiGothic-Medium.

Now Lua\TeX-ja is available from CTAN (in the \texttt{macros/\LaTeX/generic/\LaTeX\ja} directory), and the following distributions:

- \TeX Live (in \texttt{\LaTeX\dist/tex/\LaTeX\ja/\LaTeX\ja})
- W32\TeX (in \texttt{luatexja.tar.xz})
- Mi\TeX (in \texttt{luatexja.tar.lzma}); see the next subsection

Harano Aji fonts are available in \TeX Live and Mi\TeX.

\section*{HarfBuzz and Lua\TeX-ja} Using Lua\TeX-ja with LuaHB\TeX (Lua\TeX integrated with HarfBuzz) is not well tested. Maybe documents can typeset without an error, but with unwanted results (especially, vertical typesetting and \texttt{\CID}).

Especially, \textit{We don’t recommend defining a Japanese font with HarfBuzz}, by specifying \texttt{Renderer=Harfbuzz} etc. (\texttt{fontspec}) or \texttt{mode=harf} (otherwise).

\section*{Manual installation}

1. Download the source, by one of the following method. At the present, Lua\TeX-ja has no stable release.
   - Clone the Git repository by
     $ \text{git clone git://git.osdn.jp/gitroot/\LaTeX-ja/\LaTeX\ja.git}$
   - Download the \texttt{tar.gz} archive of HEAD in the \texttt{master} branch from
     \texttt{http://git.osdn.jp/view?p=\LaTeX-ja/\LaTeX\ja.git;a=snapshot;h=HEAD;sf=tgz}.

   Note that the \texttt{master} branch, and hence the archive in CTAN, are not updated frequently; the forefront of development is not the \texttt{master} branch.

2. Extract the archive. You will see \texttt{src/} and several other sub-directories. But only the contents in \texttt{src/} are needed to work Lua\TeX-ja.

3. If you downloaded this package from CTAN, you have to run following commands to generate classes and \texttt{ltj-kinsoku.lua} (the file which stores default ”kinsoku” parameters):
$ cd src
$ lualatex ltjclasses.ins
$ lualatex ltjsclasses.ins
$ lualatex ltjltxdoc.ins
$ luatex ltj-kinsoku_make.tex

Do not forget processing `ltj-kinsoku_make.tex` and `ltj-kinsoku_make.tex` used here are not needed in regular use.

4. Copy all the contents of src/ into one of your TEXMF tree. TEXMF/tex/luatex/luatexja/ is an example location. If you cloned entire Git repository, making a symbolic link of src/ instead copying is also good.

5. If `mktexlsr` is needed to update the file name database, make it so.

### 2.2 Cautions

For changes from pTeX, see Subsection 1.2.

- The encoding of your source file must be UTF-8. Other encodings, such as EUC-JP or Shift-JIS, are not supported.

- LuaTeX-ja is very slower than pTeX, and uses a lot of memory.

- **(Outdated) note for MiKTeX users**  LuaTeX-ja requires that several CMap files\(^2\) must be found from LuaTeX. Strictly speaking, those CMaps are needed only in the first run of LuaTeX-ja after installing or updating. But it seems that MiKTeX does not satisfy this condition, so you will encounter an error like the following:

  ```
  ! LuaTeX error ...les (x86)/MiKTeX 2.9/tex/luatex/luatexja/ltj-rmlgbm.lua
  bad argument #1 to 'open' (string expected, got nil)
  ```

  If so, please execute a batch file which is written on the Project Wiki (English). This batch file creates a temporary directory, copy CMaps in it, run a test file which loads LuaTeX-ja in this directory, and finally delete the temporary directory.

- Note that when LuaTeX-ja is loaded in plain LuaTeX, we cannot use color specification on font loading, such as

  ```latex
  \font\hoge=lmroman10-regular.otf:color=FF0000 % \font primitive
  ```

  This is because codes for shifting baseline in math mode (LuaTeX-ja) collide with and prevents loading codes for font color (luaotfload) in these environments. **We recommend to use b学会 2020-02-02 (or later),** since we can avoid this collision in there.

### 2.3 Using in plain \TeX

To use LuaTeX-ja in plain \TeX, simply put the following at the beginning of the document:

\input luatexja.sty

This does minimal settings (like `ptex.tex`) for typesetting Japanese documents:

- The following 12 Japanese fonts are preloaded:

<table>
<thead>
<tr>
<th>direction</th>
<th>classification</th>
<th>font name</th>
<th>“10 pt”</th>
<th>“7 pt”</th>
<th>“5 pt”</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>yoko</strong> (horizontal)</td>
<td>mincho</td>
<td>HaranoAjiMincho-Regular</td>
<td>\textmin</td>
<td>\sevenmin</td>
<td>\fivemin</td>
</tr>
<tr>
<td></td>
<td>gothic</td>
<td>HaranoAjiGothic-Medium</td>
<td>\tentgt</td>
<td>\seventgt</td>
<td>\fivetgt</td>
</tr>
<tr>
<td><strong>tate</strong> (vertical)</td>
<td>mincho</td>
<td>HaranoAjiMincho-Regular</td>
<td>\textmin</td>
<td>\sevenmin</td>
<td>\fivemin</td>
</tr>
<tr>
<td></td>
<td>gothic</td>
<td>HaranoAjiGothic-Medium</td>
<td>\tentgt</td>
<td>\seventgt</td>
<td>\fivetgt</td>
</tr>
</tbody>
</table>

- The “default” Japanese fonts (and JFMs for them) can be modified by defining \jtj@stdmcfont etc. before one inputs luatexja.sty (Subsection 7.3).
- A character in an alphabetic font is generally smaller than a Japanese font in the same size. So actual size specification of these Japanese fonts is in fact smaller than that of alphabetic fonts, namely scaled by 0.962216.

- The amount of glue that are inserted between a JAchar and an ALchar (the parameter xkanjiskip) is set to 
\[ \frac{(0.25 \cdot 0.962216 \cdot 10 \, \text{pt})^+ \text{pt} - 1 \, \text{pt}}{1 \, \text{pt}} = 2.40554 \, \text{pt} \]

2.4 Using in \LaTeX

Using in \LaTeX~2e is basically same. To set up the minimal environment for Japanese, you only have to load luatexja.sty:
\begin{verbatim}
\usepackage{luatexja}
\end{verbatim}

It also does minimal settings (counterparts in \pLaTeX are \plfonts.dtx and \pldefs.ltx).

- Font encodings for Japanese fonts are JY3 (for horizontal direction) and JT3 (for vertical direction).
- Traditionally, Japanese documents use only two families: mincho (明朝体) and gothic (ゴシック体). mincho is used in the main text, while gothic is used in the headings or for emphasis.

<table>
<thead>
<tr>
<th>classification</th>
<th>commands</th>
<th>family</th>
</tr>
</thead>
<tbody>
<tr>
<td>mincho (明朝体)</td>
<td>\textmc{...} {mcfamily ...}</td>
<td>\mcdefault</td>
</tr>
<tr>
<td>gothic (ゴシック体)</td>
<td>\textgt{...} {gtfamily ...}</td>
<td>\gtdefault</td>
</tr>
</tbody>
</table>

(Japanese counterpart for typewriter font) — — \jttdefault

Here \jttdefault specifies the Japanese font family in \verb or \verbatim environment, and its default value is \mcdefault (mincho family).\footnote{When \ltjclasses classes are used, or luatexja-fontspec (or luatexja-preset) is loaded with match option, \ttfamily changes the current Japanese font family to \jttdefault. These classes and packages also redefine \jttdefault to \gtdefault (gothic family).}

\begin{verbatim}
\renewcommand{\kanjifamilydefault}{\gtdefault}
\end{verbatim}

- By default, the following fonts are used for these two families.

<table>
<thead>
<tr>
<th>classification</th>
<th>family</th>
<th>\mdseries</th>
<th>\bfseries</th>
<th>scale</th>
</tr>
</thead>
<tbody>
<tr>
<td>mincho (明朝体)</td>
<td>mc</td>
<td>HaranoAjiMincho-Regular</td>
<td>HaranoAjiGothic-Medium</td>
<td>0.962216</td>
</tr>
<tr>
<td>gothic (ゴシック体)</td>
<td>gt</td>
<td>HaranoAjiGothic-Medium</td>
<td>HaranoAjiGothic-Medium</td>
<td>0.962216</td>
</tr>
</tbody>
</table>

- Note that the bold series (series bx or b) in both family are same as the medium series of gothic family. There is no italic nor slanted shape for these mc and gt.

- From version 20181102.0, one can specifies disablejfam option at loading Lua\TeX-ja. This option prevents loading a patch for \LaTeX, which are needed to support Japanese characters in math mode. Without disablejfam option, one can typeset Japanese characters in math mode as \$\textbf{¥}$ (see Page 11) as before. Japanese characters in math mode are typeset by the font family mc.

- If you use the beamer class with the default font theme (which uses sans serif fonts) and with Lua\TeX-ja, you might want to change default Japanese fonts to the gothic family. The following line changes the default Japanese font family to it:
\begin{verbatim}
\renewcommand{\kanjifamilydefault}{\gtdefault}
\end{verbatim}
However, above settings are not sufficient for Japanese-based documents. To typeset Japanese-based documents, you are better to use class files other than article.cls, book.cls, and so on. At the present, Lua\TeX-ja has the counterparts of jclasses (standard classes in \TeX) and jsclasses (classes by Haruhiko Okumura), namely, ltjclasses\(^4\) and ltjsclasses\(^5\).

Original jsclasses use \textbackslash mag primitive to set the main document font size. However, Lua\TeX does not support \textbackslash mag in PDF output, so ltjsclasses uses the nomag* option\(^6\) by default to set the main font size. If this causes some unexpected behavior, specify nomag option in \textbackslash documentclass.

\section*{\textit{\textbf{geom}}etry package and classes for \textbf{\textsc{vertical writing}}} It is well-known that the geometry package produces the following error, when classes for vertical writing is used:
\begin{verbatim}
! Incompatible direction list can’t be unboxed. \begindvi \unvbox \begindvibox \global \let \begindvi \empty
\end{verbatim}

Now, Lua\TeX-ja automatically applies the patch lltjp-geometry to the geometry package, when the direction of the document is \textit{tate} (vertical writing). This patch lltjp-geometry also can be used in \TeX; for the detail, please refer \texttt{lltjp-geometry.pdf} (Japanese).

\section{Changing Fonts}

\subsection{plain \textsc{\TeX} and \textsc{\LaTeX} 2e}

\subsection*{plain \textsc{\TeX}} To change Japanese fonts in plain \TeX, you must use the command \texttt{\jfont} and \texttt{\jfont}. So please see Subsection 7.1.

\subsection*{\textsc{\LaTeX} 2e (NFSS2)} For \textsc{\LaTeX} 2e, Lua\TeX-ja adopted most of the font selection system of \textsc{\LaTeX} 2e (in \texttt{plfonts.dtx}).

\begin{longtable}{|c|c|c|c|c|}
\hline
encoding & family & series & shape & selection \\
\hline
Alphabetic fonts & romanencoding & romanfamily & romanseries & romanshape & userroman \\
Japanese fonts & kanjienencoding & kanjifamily & kanjiseries & kanjishape & usekanji \\
both & - & - & \fontseries & \fontshape & - \\
auto select & \fontencoding & \fontfamily & - & - & usefont \\
\hline
\end{longtable}

- \texttt{\fontfamily}, \texttt{\fontseries}, and \texttt{\fontshape} try to change attributes of Japanese fonts, as well as those of alphabetic fonts. Of course, \texttt{\selectfont} is needed to select current text fonts.

Note that \texttt{\fontshape} always changes current alphabetic font shape, but it does not change current Japanese font shape if the target shape is unavailable for current Japanese encoding/family/series. For the detail, see Subsection 10.2.

- \texttt{\fontencoding}{\langle encoding \rangle} changes the encoding of alphabetic fonts or Japanese fonts depending on the argument. For example, \texttt{\fontencoding{JY3}} changes the encoding of Japanese fonts to JY3, and \texttt{\fontencoding{T1}} changes the encoding of alphabetic fonts to T1. \texttt{\fontfamily} also changes the current Japanese font family, the current alphabetic font family, or \textit{both}. For the detail, see Subsection 10.2.

- For defining a Japanese font family, use \texttt{\DeclareKanjiFamily} instead of \texttt{\DeclareFontFamily}. (In previous version of Lua\TeX-ja, using \texttt{\DeclareFontFamily} didn’t cause any problem. But this no longer applies the current version.)

- Defining a Japanese font shape can be done by usual \texttt{\DeclareFontShape}:
\begin{verbatim}
\DeclareFontShape{JY3}{mc}{b}{n}{<-> s*HaranoAjiMincho--Bold:jfm=ujis;-kern}{% Harano Aji Mincho Bold
\end{verbatim}

\(^4\)ltjarticle.cls, ltjbook.cls, ltjreport.cls, ltjtarticle.cls, ltjbook.cls, ltjreport.cls. The latter ltjt*.cls are for vertically written Japanese documents.

\(^5\)ltjsarticle.cls, ltjsbook.cls, ltjsreport.cls, ltjsarticle.cls, ltjsbook.cls, ltjsreport.cls. ltjskiyou.cls.

\(^6\)Same effect as the BXjscls classes (by Takayuki Yato) and jsclasses. However, these classes uses only \TeX code, but ltjsclasses uses Lua code.
Table 1. Commands of luatexja-fontspec

**Japanese characters in math mode**

Since \TeX supports Japanese characters in math mode, there are sources like the following:

1. $f_\text{高温}$ \(\equiv f_{\text{high temperature}}\).
2. \[ y = (x-1)^2 + 2 \quad \text{よって} \quad y > 0 \]
3. $5 \in \text{素} := \{ p \in \mathbb{N} : p \text{ is a prime} \}$.

We (the project members of Lua\TeX-ja) think that using Japanese characters in math mode are allowed if and only if these are used as identifiers. In this point of view,

- The lines 1 and 2 above are not correct, since “高温” in above is used as a textual label, and “よって” is used as a conjunction.

- However, the line 3 is correct, since “素” is used as an identifier.

Hence, in our opinion, the above input should be corrected as:

1. $f_\text{高温}$ \(\equiv f_{\text{high temperature}}\).
2. \[ y = (x-1)^2 + 2 \quad \text{よって} \quad y > 0 \]
3. $5 \in \text{素} := \{ p \in \mathbb{N} : p \text{ is a prime} \}$.

We also believe that using Japanese characters as identifiers is rare, hence we don’t describe how to change Japanese fonts in math mode in this chapter. For the method, please see Subsection 7.6.

When Lua\TeX-ja is loaded with `disablejfam` option, one cannot write Japanese characters in math mode as \text{素}. At that case, one have to use \texttt{\mbox} (or \texttt{\text} in the amsmath package).

### 3.2 luatexja-fontspec package

To use the functionality of the fontspec package to Japanese fonts, it is needed to load the luatexja-fontspec package in the preamble, as follows:

```
\usepackage[⟨options⟩]{luatexja-fontspec}
```

This luatexja-fontspec package automatically loads luatexja and fontspec packages, if needed.

In the luatexja-fontspec package, several commands are defined as counterparts of original commands in the fontspec package (see Table 1):

The package option of luatexja-fontspec are the followings:

**match**

If this option is specified, usual family-changing commands such as \texttt{\rmfamily}, \texttt{\textrm}, \texttt{\sffamily}, ... also change Japanese font family.

**pass=⟨opts⟩**

(Obsoleted) Specify options ⟨opts⟩ which will be passed to the fontspec package.
Override the ratio of the font size of Japanese fonts to that of alphabetic fonts. The default value is determined as follows:

- The value of \Cjascale is used, if this control sequence is already defined.
- It is calculated automatically from the current Japanese font at the loading of the package, if \Cjascale is not defined.

\Cjascale is defined in \ltjclasses and \ltjsclasses.

All other options listed above are simply passed to the fontspec package. This means that two lines below are equivalent, for example.
\usepackage[no-math]{fontspec}\usepackage{luatexja-fontspec}
\usepackage[no-math]{luatexja-fontspec}

Note that kerning information in a font is not used (that is, kern feature is set off) by default in these seven (or eight) commands. This is because of the compatibility with previous versions of \LaTeXX-ja (see 7.1).

Below is an example of \jfontspec.
\begin{verbatim}
\jfontspec[CJKShape=NLC]{HaranoAjiMincho-Regular}
\jfontspec[CJKShape=JIS1990]{HaranoAjiMincho-Regular}
\jfontspec[CJKShape=JIS1978]{HaranoAjiMincho-Regular}
\end{verbatim}

3.3 Presets of Japanese fonts

With \luatexja-preset package, one use one of “preset” to simplify Japanese font setting. For details of package options, and those of each presets, please see Subsection 11.6. The following presets are defined:

haranoaji, hiragino-pro, hiragino-pron, ipa, ipa-hg, ipaex, ipaex-hg, kozuka-pr6, kozuka-pr6n, kozuka-pro, moga-mobo, moga-mobo-ex, bizud, morisawa-pr6, morisawa-pro, ms, ms-hg, noembed, noto-otc, noto-otf, sourcehan, sourcehan-jp, uma, yu-osx, yu-win, yu-win10

For example, this document loads \luatexja-preset package by
\usepackage[haranoaji]{luatexja-preset}
which means that Harano Aji fonts will be used in this document.

3.4 \CID, \UTF, and macros in \japanese-otf package

Under \japanese-otf package (developed by Shuzaburo Saito) is used for typesetting characters which is in Adobe-Japan1-6 CID but not in JIS X 0208. Since this package is widely used, Lua\TeXX-ja supports some of functions in the japanese-otf package, as an external package \luatexja-otf.

Changing Internal Parameters

There are many internal parameters in \LaTeXX-ja. And due to the behavior of \LaTeXX, most of them are not stored as internal register of \LaTeX, but as an original storage system in \LaTeX-ja. Hence, to assign or acquire those parameters, you have to use commands \ltjsetparameter and \ltjgetparameter.

4.1 Range of JAchars

LuaTeX-ja divides the Unicode codespace U+0080–U+10FFFF into character ranges, numbered 1 to 217. The grouping can be (globally) customized by \ltjdefcharrange. The next line adds whole characters in Supplementary Ideographic Plane and the character “漢” to the character range 100.

\ltjdefcharrange{100}{“20000-”2FFFF,`漢}

A character can belong to only one character range. For example, whole SIP belong to the range 4 in the default setting of LuaTeX-ja, and if one executes the above line, then SIP will belong to the range 100 and be removed from the range 4.

The distinction between ALchar and JAchar is performed by character ranges. This can be edited by setting the jacharrange parameter. For example, the code below is just the default setting of LuaTeX-ja, and it sets

- a character which belongs character ranges 1, 4, 5, and 8 is ALchar,
- a character which belongs character ranges 2, 3, 6, 7, and 9 is JAchar.

\ltjsetparameter{jacharrange={-1, +2, +3, -4, -5, +6, +7, -8, +9}}

The argument to jacharrange parameter is a list of non-zero integer. Negative integer −n in the list means that “each character in the range n is an ALchar”, and positive integer +n means that “... is a JAchar”.

Note that characters U+0000–U+007F are always treated as an ALchar (this cannot be customized).

Default character ranges LuaTeX-ja predefines nine character ranges for convenience. They are determined from the following data:

- Blocks in Unicode 12.0.0.
- The PXbase bundle for upTeX by Takayuki Yato.

Now we describe these nine ranges. The superscript “J” or “A” after the number shows whether each character in the range is treated as JAchars or not by default. These settings are similar to the prefercjk settings defined in PXbase bundle. Any characters equal to or above U+0080 which does not belong to these eight ranges belongs to the character range 217.

Range 8^A The intersection of the upper half of ISO 8859-1 (Latin-1 Supplement) and JIS X 0208 (a basic character set for Japanese). The character list is indicated in Table 2.

Range 1^A Latin characters that some of them are included in Adobe-Japan1-7. This range consists of the Unicode ranges indicated in Table 3, except characters in the range 8 above.

Range 2^A Greek and Cyrillic letters. JIS X 0208 (hence most of Japanese fonts) has some of these characters.

</tbody>
</table>

For example, \Frowny which is provided by the marvosym package has the same codepoint as § (U+00A7). Hence, as previous versions of Lua\TeX-ja, if these characters are treated as JAchars, then \Frowny produces “§” (in a Japanese font).

To avoid such situations, the default setting of Lua\TeX-ja is changed in version 20150906.0 so that all characters U+0080–U+00FF are treated as ALchar.

If you want to output a character as ALchar and JAchar regardless the range setting, you can use \ltjalchar and \ltjjachar respectively, as the following example.

\begin{verbatim}
\gfamily\large % default, ALchar, JAchar
\% §, \ltjalchar\%, \ltjjachar\%\} % default: ALchar
\% \, \ltjalchar\, \, \ltjjachar\, % default: JAchar
\end{verbatim}

4.2 **kanjiskip and xkanjiskip**

JAglue is divided into the following three categories:

- Glues/kerns specified in JFM. If \inhibitglue is issued around a JAchar, this glue will not be inserted at the place.
- The default glue which inserted between two JAchars (kanjiskip).
- The default glue which inserted between a JAchar and an ALchar (xkanjiskip).

The value (a skip) of kanjiskip or xkanjiskip can be changed as the following. Note that only their values at the end of a paragraph or a hbox are adopted in the whole paragraph or the whole hbox.

\begin{verbatim}
\ltjsetparameter{kanjiskip={0pt plus 0.4pt minus 0.4pt},
                   xkanjiskip={0.25*pz plus 1pt minus 1pt}}
\end{verbatim}

Here \pz is a internal dimension which stores fullwidth of the current Japanese font. This \pz can be used as the unit zw in \Lmptx.

The value of these parameter can be get by \ltjgetparameter. Note that the result by \ltjgetparameter is not the internal quantities, but a string (hence \the cannot be prefixed).

\begin{verbatim}
kanjiskip: \ltjgetparameter[kanjiskip],\% kanjiskip: 0.0pt plus 0.4pt minus 0.5pt,
\end{verbatim}

\begin{verbatim}
xkanjiskip: \ltjgetparameter[xkanjiskip] xkanjiskip: 2.40555pt plus 1pt minus 1.0pt
\end{verbatim}

It may occur that JFM contains the data of “ideal width of kanjiskip” and/or “ideal width of xkanjiskip”. To use these data from JFM, set the value of kanjiskip or xkanjiskip to \maxdimen (these “ideal width” cannot be retrieved by \ltjgetparameter).
4.3 Insertion setting of \texttt{xkanjiskip}

It is not desirable that \texttt{xkanjiskip} is inserted into every boundary between \texttt{Jachs} and \texttt{ALchar}s. For example, \texttt{xkanjiskip} should not be inserted after opening parenthesis (e.g., compare “（あ” and “（あ”). Lua\TeX-ja can control whether \texttt{xkanjiskip} can be inserted before/after a character, by changing \texttt{jaxspmode} for \texttt{Jachs} and \texttt{alxspmode} parameters \texttt{ALchar}s respectively.

\begin{verbatim}
\ltjsetparameter{jaxspmode={``あ,preonly}, alxspmode={``!,postonly}}
\end{verbatim}

The second argument \texttt{preonly} means that the insertion of \texttt{xkanjiskip} is allowed before this character, but not after. The other possible values are \texttt{postonly}, \texttt{allow}, and \texttt{inhibit}.

\texttt{jaxspmode} and \texttt{alxspmode} use a same table to store the parameters on the current version. Therefore, line 1 in the code above can be rewritten as follows:

\begin{verbatim}
\ltjsetparameter{alxspmode={``あ,preonly}, jaxspmode={``!,postonly}}
\end{verbatim}

One can use also numbers to specify these two parameters (see Subsection 8.1).

If you want to enable/disable all insertions of \texttt{kanjiskip} and \texttt{xkanjiskip}, set \texttt{autospacing} and \texttt{autoxspacing} parameters to \texttt{true}/\texttt{false}, respectively.

4.4 Shifting the baseline

To make a match between a Japanese font and an alphabetic font, sometimes shifting of the baseline of one of the pair is needed. In \texttt{p\TeX}, this is achieved by setting \texttt{\ybaselineshift} (or \texttt{\tbaselineshift}) to a non-zero length (the baseline of \texttt{ALchar} is shifted below). However, for documents whose main language is not Japanese, it is good to shift the baseline of Japanese fonts, but not that of alphabetic fonts. Because of this, Lua\TeX-ja can independently set the shifting amount of the baseline of alphabetic fonts and that of Japanese fonts.

<table>
<thead>
<tr>
<th>Horizontal writing (yoko direction) etc.</th>
<th>Vertical writing (tate direction)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alphabetic fonts</td>
<td>\texttt{yalbaselineshift} parameter</td>
</tr>
<tr>
<td>Japanese fonts</td>
<td>\texttt{yjabaselineshift} parameter</td>
</tr>
<tr>
<td></td>
<td>\texttt{talbaselineshift} parameter</td>
</tr>
<tr>
<td></td>
<td>\texttt{tjabaselineshift} parameter</td>
</tr>
</tbody>
</table>

Here the horizontal line in the below example is the baseline of a line.

\begin{verbatim}
\vrule width 150pt height 0.2pt depth 0.2pt \hskip-120pt
\ltjsetparameter{yjabaselineshift=0pt, yalbaselineshift=0pt}abcあいう
\ltjsetparameter{yjabaselineshift=5pt, yalbaselineshift=2pt}abcあいう
\end{verbatim}

There is an interesting side-effect: characters in different size can be vertically aligned center in a line, by setting two parameters appropriately. The following is an example (beware the value is not well tuned):

\begin{verbatim}
\vrule width 150pt height 4.417pt depth -4.217pt\
\kern-150pt\
\large xyz漢字\
\{\scriptsize\
\ltjsetparameter{yjabaselineshift=-1.757pt, yalbaselineshift=-1.757pt}\}
\end{verbatim}

Note that setting positive \texttt{yalbaselineshift} or \texttt{talbaselineshift} parameters does not increase the depth of one-letter syllable \textit{p} of \texttt{Alchar}, if its left-protrusion (\texttt{\lpcode}) and right-protrusion (\texttt{\rpcode}) are both non-zero. This is because

- These two parameters are implemented by setting \texttt{yoffset} field of a glyph node, and this does not increase the depth of the glyph.
• To cope with the above situation, LuaTeX-ja automatically supplies a rule in every syllable.

• However, we cannot use this “supplying a rule” method if a syllable comprises just one letter whose \lpcode and \rpcode are both non-zero.

This problem does not apply for \vjabaselineshift or \tjabaselineshift, because a JAchar is encapsulated by a horizontal box if needed.

4.5 **kinsoku parameters and OpenType features**

Among parameters which related to Japanese word-wrapping process (*kinsoku shori*),

\jaxspmode, \alxspmode, \prebreakpenalty, \postbreakpenalty and \kcatcode

are stored by each character codes.

OpenType font features are ignored in these parameters. For example, a fullwidth katakana “ア” on line 10 in the below input is replaced to its halfwidth variant “ｱ”, by \hwid feature. However, the penalty inserted after it is 10 which is the \postbreakpenalty of “ｱ”, not 20.

```
1 \ltxsetparameter{postbreakpenalty={‘ア’, 10}}
2 \ltxsetparameter{postbreakpenalty={‘ｱ’, 20}}
3 \newcommand\showpostpena[1][]{% #1}
4 \leavevmode\setbox0=\hbox{#1}\hbox{%}
5 \unhbox0\setbox0=\lastbox\the\lastpenalty
6 \showpostpena{ア},
7 \showpostpena{ｱ},
8 {\addjfontfeatures{CharacterWidth=Half}\showpostpena{ア}}
```

5 \texttt{\textbackslash catcode} in \texttt{Lua\TeX}\texttt{-ja}

5.1 Preliminaries: \texttt{\textbackslash catcode} in \texttt{p\TeX} and \texttt{up\TeX}

In \texttt{p\TeX} and \texttt{up\TeX}, the value of \texttt{\textbackslash catcode} determines whether a Japanese character can be used in a control word. For the detail, see Table 8.

\texttt{\textbackslash catcode} can be set by a row of JIS X 0208 in \texttt{p\TeX}, and generally by a Unicode block\textsuperscript{7} in \texttt{up\TeX}. So characters which can be used in a control word slightly differ between \texttt{p\TeX} and \texttt{up\TeX}.

5.2 Case of \texttt{Lua\TeX}\texttt{-ja}

The role of \texttt{\textbackslash catcode} in \texttt{p\TeX} and \texttt{up\TeX} can be divided into the following four kinds, and \texttt{Lua\TeX}\texttt{-ja} can control these four kinds separately:

- Distinction between \texttt{\textbackslash JAchar} or \texttt{\textbackslash ALchar} is controlled by the character range, see Subsection 4.1.
- Whether the character can be used in a control word is controlled by setting \texttt{\textbackslash catcode} to 11 (enabled) or 12 (disabled), as usual.
- Whether \texttt{\textbackslash icharwidthpenalty} can be inserted before the character is controlled by the lowermost bit of the \texttt{\textbackslash catcode} parameter.
- Linebreak after a \texttt{\textbackslash JAchar} does not produce a space.

Default setting of \texttt{\textbackslash catcode} of Unicode characters are located in \texttt{plain Lua\TeX} \texttt{luatex-unicode-letters.tex}, which is based on \texttt{unicode-letters.tex} (for Xe\TeX).

\texttt{Lua\TeX} now included in \texttt{\TeX} kernel as \texttt{unicode-letters.def}.

However, the default setting of \texttt{\textbackslash catcode} differs between Xe\TeX and Lua\TeX, by the following reasons:

- (plain format) \texttt{luatex-unicode-letters.tex} is based on old \texttt{unicode-letters.tex}.
- The latter half of \texttt{unicode-letters.tex} and \texttt{unicode-letters.def} sets\texttt{\textbackslash catcode} of several characters to 11, via setting \texttt{\textbackslash XeTeXcharclass}. However, this latter half does not exist (plain case), or not executed (\texttt{\TeX} case) in Lua\TeX.

In other words,

\texttt{plain Lua\TeX} Kanji nor kana characters cannot be used in a control word, in the default setting of plain Lua\TeX.

\texttt{Lua\TeX} In recent (2015-10-01 or later) Lua\TeX, Kanji and kana characters in a control word is supported (these catcode are 11), but not fullwidth alphanumerics and several other characters.

This would be inconvenient for \texttt{p\TeX} users to shifting to Lua\TeX\texttt{-ja}, since several control words containing Kanji or other fullwidth characters, such as \texttt{\textbackslash 西暦} or \texttt{\textbackslash 1年目西暦} are used in \texttt{p\TeX}. Hence, Lua\TeX\texttt{-ja} have a counterpart of \texttt{unicode-letters.tex} for Lua\TeX, to match the \texttt{\textbackslash catcode} setting with that of Xe\TeX.

5.3 Non-kanji characters in a control word

Because the engine differ, so non-kanji JIS X 0208 characters which can be used in a control word differ in \texttt{p\TeX}, in \texttt{up\TeX}, and in Lua\TeX\texttt{-ja}. Table 9 shows the difference. Except for four characters “・”, “゛”, “゜”, “゠”, Lua\TeX\texttt{-ja} admits more characters in a control word than \texttt{up\TeX}.

Difference becomes larger, if we consider non-kanji JIS X 0213 characters. For the detail, see \url{https://github.com/h-kitagawa/kct}.

\textsuperscript{7}up\TeX divides U+FF00–U+FFEF (Halfwidth and Fullwidth Forms) into three subblocks, and \texttt{\textbackslash catcode} can be set by a subblock.
6 Directions

LuaTEX supports four Ω-style directions: TLT, TRT, RTT and LTL. However, neither directions are not well-suited for typesetting Japanese vertically, hence we implemented vertical writing by rotating TLT-box by 90 degrees.

LuaTEX-ja supports four directions, as shown in Table 10. The second column (yoko direction) is just horizontal writing, and the third column (tate direction) is vertical writing. The fourth column (dtou direction) is actually a hidden feature of pTEX. We implemented this for debugging purpose. The fifth column (utod direction) corresponds the “tate (math) direction” of pTEX.

Directions can be changed by \yoko, \tate, \dtou, \utod, only when the current list is null. These commands cannot be executed in unrestricted horizontal modes, nor math modes. The direction of a math formula is changed to utod, when the direction outside the math formula is tate (vertical writing).

6.1 Boxes in different direction

As in pTEX, one can use boxes of different direction in one document. The below is an example.

### Table 8. \kcatcode in up\TeX

<table>
<thead>
<tr>
<th>(Notation used in Ω)</th>
<th>TLT</th>
<th>RTR, RTT</th>
<th>LBL</th>
<th>RTR</th>
</tr>
</thead>
</table>

Table 11 shows how a box is arranged when the direction inside the box and that outside the box differ.

\[\textbf{∥w\ and direction} \quad \text{In p TeX, } \texttt{∥w}, \texttt{∥ht}, \texttt{∥dp} \text{ means the dimensions of a box register with respect to the current direction. This means that the value of } \texttt{∥w0} \text{ etc. might differ when the current direction is different, even if } \texttt{∥box0} \text{ stores the same box. However, this no longer applies in LuaTeX-ja.}

\[\begin{align*}
1. & \texttt{∥setbox0=∥box to 20pt\{foo\}} \\
2. & \texttt{∥the\{∥w0,∥ht,∥dp\}} \\
3. & \texttt{∥w0=10pt} \\
4. & \texttt{∥the\{∥w0,∥ht,∥dp\}} \quad \text{20.0pt, 100.0pt, 100.0pt}
\end{align*}\]

To access box dimensions with respect to current direction, one have to use the following commands instead of \texttt{∥w} wtc.

\[\texttt{∥ltjgetwd(n),∥ltjgetht(n),∥ltjgetdp(n)}\]

These commands return an internal dimension of \texttt{∥box(n)} with respect to the current direction. One can use these in \texttt{∥dimexpr} primitive, as the followings.

\[\begin{align*}
\text{∥dimexpr 2\{∥ltjgetwd42-3pt\}relax, \∥the\{∥ltjgetwd1701} \quad \text{YOKO} \quad 38.48877pt, 8.46753pt, 1.15466pt.
\end{align*}\]
Table 11. Boxes in different direction

<table>
<thead>
<tr>
<th>typeset in yoko direction</th>
<th>typeset in tate or utod direction</th>
<th>typeset in dtou direction</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

\[ W_y = h_y + d_y, \]
\[ H_y = w_y, \]
\[ D_y = 0 \text{ pt} \]

\[ W_T = h_T + d_T, \]
\[ H_T = w_T, \]
\[ D_T = w_T/2 \]

\[ W_D = h_T + d_T, \]
\[ H_D = w_T, \]
\[ D_D = 0 \text{ pt} \]

\[ \ltjsetwd⟨num⟩=⟨dimen⟩, \ltjsetht⟨num⟩=⟨dimen⟩, \ltjsetdp⟨num⟩=⟨dimen⟩ \]
These commands set the dimension of \textbackslash box⟨num⟩. One does not need to group the argument \langle num⟩; four calls of \textbackslash ltjsetwd below have the same meaning.

\[ \ltjsetwd42 20\text{pt}, \ltjsetwd42=20\text{pt}, \ltjsetwd=42 20\text{pt}, \ltjsetwd=42=20\text{pt} \]

6.2 Getting current direction

The direction parameter returns the current direction, and the boxdir parameter (with the argument \langle num⟩) returns the direction of a box register \textbackslash box⟨num⟩. The returned value of these parameters are a string:

<table>
<thead>
<tr>
<th>Direction</th>
<th>yoko</th>
<th>tate</th>
<th>dtou</th>
<th>utod</th>
<th>(empty)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned value</td>
<td>4</td>
<td>3</td>
<td>1</td>
<td>11</td>
<td>0</td>
</tr>
</tbody>
</table>

3 \hbox{\tate} \hbox{\tate math: \DIR}\
4 \ltjsetwd42 20\text{pt}, \ltjsetwd42=20\text{pt}, \ltjsetwd=42 20\text{pt}, \ltjsetwd=42=20\text{pt}
Table 12. Differences between horizontal JFMs shipped with LuaTeX-ja

| Blue: jfm-ujis.lua, Black: jfm-jis.lua, Red: jfm-min.lua |

6.3 Overridden box primitives

To cope with multiple directions, the following primitives are overridden by LuaTeX-ja, using \protected\def.

\unhbox{num}, \unvbox{num}, \unhcopy{num}, \unvcopy{num}
\vadjust{⟨material⟩}
\insert{number}{⟨material⟩}
\vcenter

7 Font Metric and Japanese Font

7.1 \jfont

To load a font as a Japanese font (for horizontal direction), you must use the \jfont instead of \font, while \jfont admits the same syntax used in \font. LuaTeX-ja automatically loads luaotfload package, so TrueType/OpenType fonts with features can be used for Japanese fonts:

\jfont\tradmc={IPAexMincho:script=latn;\+trad;-kern;jfm=ujis} at 14pt
\jfont 当／体／医／区

Note that the defined control sequence (\tradmc in the example above) using \jfont is not a font_def token, but a macro. Hence the input like \fontname\tradmc causes an error. We denote control sequences which are defined in \jfont by ⟨jfont_cs⟩.

JFM  a JFM has measurements of characters and glues/kerns that are automatically inserted for Japanese typesetting. The structure of JFM will be described in the next subsection. At the calling of \jfont, you must specify which JFM will be used for this font by the following keys:

jfm=⟨name⟩

Specify the name of (horizontal) JFM. If specified JFM has not been loaded, LuaTeX-ja search and load a file named jfm-⟨name⟩.lua.

The following horizontal JFMs are shipped with LuaTeX-ja:

jfm-ujis.lua A standard horizontal JFM in LuaTeX-ja. This JFM is based on upnmlminr-h.tfm, a metric for UTF/OTF package that is used in upTeX. When you use the luatexja-otf package, you should use this JFM.
Figure 1. Example of jfmvar key

Figure 2. Kerning information and \texttt{kanjiskip}

\texttt{jfm-jis.lua} A counterpart for \texttt{jis.tfm}, "JIS font metric" which is widely used in \LaTeX. A major difference between \texttt{jfm-ujis.lua} and this \texttt{jfm-jis.lua} is that most characters under \texttt{jfm-ujis.lua} are square-shaped, while that under \texttt{jfm-jis.lua} are horizontal rectangles.

\texttt{jfm-min.lua} A counterpart for \texttt{min10.tfm}, which is one of the default Japanese font metric shipped with \LaTeX.

The difference among these three JFMs is shown in Table 12.

\texttt{jfmvar=(string)} Sometimes there is a need that ....

\section*{Using kerning information in a font} Some fonts have information for inter-glyph spacing. Lua\TeX-ja 20140324.0 or later treats kerning spaces like an italic correction; any glue and/or kern from the JFM and a kerning space can coexist. See Figure 2 for detail.

Note that in \texttt{\setmainfont} etc. which are provided by luatexja-fontspec package, kerning option is set \texttt{off} (\texttt{Kerning=Off}) by default, because of the compatibility with previous versions of Lua\TeX-ja.

\section*{extend and slant} The following setting can be specified as OpenType font features:

\texttt{extend=(extend)} expand the font horizontally by \texttt{(extend)}.
\texttt{slant=\langle slant \rangle} \text{slant the font.}

Note that Lua\TeX-ja doesn’t adjust JFMs by these \texttt{extend} and \texttt{slant} settings; you have to write new JFMs on purpose. For example, the following example uses the standard JFM \texttt{jfm-ujis.lua}, hence letter-spacing and the width of italic correction are not correct:

1 \texttt{\jfont\E=HaranoAjiMincho-Regular:extend=1.5;jfm=ujis;-kern}
2 \texttt{\jfont\S=HaranoAjiMincho-Regular:slant=1;jfm=ujis;-kern}
3 \texttt{E あいうえお \ S あいう \ ABC}

\texttt{\ltjksp} \text{kanjiskip\_natural, kanjiskip\_stretch, kanjiskip\_shrink keys (Page ??) makes the Lua\TeX-ja inserts not only a glue which is specified by a JFM, and also the natural width/stretch part/shrink part of \texttt{kanjiskip}.}

This functionality is disabled by \texttt{-ltjksp} specification.

1 \texttt{\leavevmode}
2 \texttt{\ltjsetparameter\{kanjiskip=0pt plus 3\zw\}}
3 \texttt{\vrule\hbox to 15\zw{あ「い」う, えお}\vrule\}
4 \texttt{\jfont\G=HaranoAjiMincho-Regular:jfm=ujisv\%}
5 \texttt{\vrule\hbox to 15\zw{あ「い」う, えお}\vrule\}
6 \texttt{\G\leavevmode\%}
7 \texttt{\vrule\hbox to 15\zw{あ「い」う, えお}\vrule}

### 7.2 \texttt{tfont}

\texttt{tfont} loads a font as a Japanese font for vertical direction. This command admits the same syntax used in \texttt{\jfont} and \texttt{\font}. A font defined by \texttt{\jfont} differs the following points from that by \texttt{\jfont}:

- \texttt{\jfont\E=HaranoAjiMincho-Regular:extend=1.5;jfm=ujis;-kern}
- \texttt{\jfont\S=HaranoAjiMincho-Regular:slant=1;jfm=ujis;-kern}

- \texttt{E あいうえお \ S あいう \ ABC}

- \texttt{\ltjksp} \text{kanjiskip\_natural, kanjiskip\_stretch, kanjiskip\_shrink keys (Page ??) makes the Lua\TeX-ja inserts not only a glue which is specified by a JFM, and also the natural width/stretch part/shrink part of \texttt{kanjiskip}.}

This functionality is disabled by \texttt{-ltjksp} specification.

1 \texttt{\leavevmode}
2 \texttt{\ltjsetparameter\{kanjiskip=0pt plus 3\zw\}}
3 \texttt{\vrule\hbox to 15\zw{あ「い」う, えお}\vrule\}
4 \texttt{\jfont\G=HaranoAjiMincho-Regular:jfm=ujisv\%}
5 \texttt{\vrule\hbox to 15\zw{あ「い」う, えお}\vrule\}
6 \texttt{\G\leavevmode\%}
7 \texttt{\vrule\hbox to 15\zw{あ「い」う, えお}\vrule}

#### 7.2.1 \texttt{tfont}

\texttt{tfont} loads a font as a Japanese font for vertical direction. This command admits the same syntax used in \texttt{\jfont} and \texttt{\jfont}. A font defined by \texttt{\jfont} differs the following points from that by \texttt{\jfont}:

- \texttt{\jfont\E=HaranoAjiMincho-Regular:extend=1.5;jfm=ujis;-kern}
- \texttt{\jfont\S=HaranoAjiMincho-Regular:slant=1;jfm=ujis;-kern}

- \texttt{E あいうえお \ S あいう \ ABC}

- \texttt{\ltjksp} \text{kanjiskip\_natural, kanjiskip\_stretch, kanjiskip\_shrink keys (Page ??) makes the Lua\TeX-ja inserts not only a glue which is specified by a JFM, and also the natural width/stretch part/shrink part of \texttt{kanjiskip}.}

This functionality is disabled by \texttt{-ltjksp} specification.

1 \texttt{\leavevmode}
2 \texttt{\ltjsetparameter\{kanjiskip=0pt plus 3\zw\}}
3 \texttt{\vrule\hbox to 15\zw{あ「い」う, えお}\vrule\}
4 \texttt{\jfont\G=HaranoAjiMincho-Regular:jfm=ujisv\%}
5 \texttt{\vrule\hbox to 15\zw{あ「い」う, えお}\vrule\}
6 \texttt{\G\leavevmode\%}
7 \texttt{\vrule\hbox to 15\zw{あ「い」う, えお}\vrule}

#### 7.2.1 \texttt{tfont}

\texttt{tfont} loads a font as a Japanese font for vertical direction. This command admits the same syntax used in \texttt{\jfont} and \texttt{\jfont}. A font defined by \texttt{\jfont} differs the following points from that by \texttt{\jfont}:

- \texttt{\jfont\E=HaranoAjiMincho-Regular:extend=1.5;jfm=ujis;-kern}
- \texttt{\jfont\S=HaranoAjiMincho-Regular:slant=1;jfm=ujis;-kern}

- \texttt{E あいうえお \ S あいう \ ABC}

- \texttt{\ltjksp} \text{kanjiskip\_natural, kanjiskip\_stretch, kanjiskip\_shrink keys (Page ??) makes the Lua\TeX-ja inserts not only a glue which is specified by a JFM, and also the natural width/stretch part/shrink part of \texttt{kanjiskip}.}

This functionality is disabled by \texttt{-ltjksp} specification.

1 \texttt{\leavevmode}
2 \texttt{\ltjsetparameter\{kanjiskip=0pt plus 3\zw\}}
3 \texttt{\vrule\hbox to 15\zw{あ「い」う, えお}\vrule\}
4 \texttt{\jfont\G=HaranoAjiMincho-Regular:jfm=ujisv\%}
5 \texttt{\vrule\hbox to 15\zw{あ「い」う, えお}\vrule\}
6 \texttt{\G\leavevmode\%}
7 \texttt{\vrule\hbox to 15\zw{あ「い」う, えお}\vrule}

#### 7.2.1 \texttt{tfont}

\texttt{tfont} loads a font as a Japanese font for vertical direction. This command admits the same syntax used in \texttt{\jfont} and \texttt{\jfont}. A font defined by \texttt{\jfont} differs the following points from that by \texttt{\jfont}:

- \texttt{\jfont\E=HaranoAjiMincho-Regular:extend=1.5;jfm=ujis;-kern}
- \texttt{\jfont\S=HaranoAjiMincho-Regular:slant=1;jfm=ujis;-kern}

- \texttt{E あいうえお \ S あいう \ ABC}

- \texttt{\ltjksp} \text{kanjiskip\_natural, kanjiskip\_stretch, kanjiskip\_shrink keys (Page ??) makes the Lua\TeX-ja inserts not only a glue which is specified by a JFM, and also the natural width/stretch part/shrink part of \texttt{kanjiskip}.}

This functionality is disabled by \texttt{-ltjksp} specification.

1 \texttt{\leavevmode}
2 \texttt{\ltjsetparameter\{kanjiskip=0pt plus 3\zw\}}
3 \texttt{\vrule\hbox to 15\zw{あ「い」う, えお}\vrule\}
4 \texttt{\jfont\G=HaranoAjiMincho-Regular:jfm=ujisv\%}
5 \texttt{\vrule\hbox to 15\zw{あ「い」う, えお}\vrule\}
6 \texttt{\G\leavevmode\%}
7 \texttt{\vrule\hbox to 15\zw{あ「い」う, えお}\vrule}

#### 7.2.1 \texttt{tfont}

\texttt{tfont} loads a font as a Japanese font for vertical direction. This command admits the same syntax used in \texttt{\jfont} and \texttt{\jfont}. A font defined by \texttt{\jfont} differs the following points from that by \texttt{\jfont}:

- \texttt{\jfont\E=HaranoAjiMincho-Regular:extend=1.5;jfm=ujis;-kern}
- \texttt{\jfont\S=HaranoAjiMincho-Regular:slant=1;jfm=ujis;-kern}

- \texttt{E あいうえお \ S あいう \ ABC}

- \texttt{\ltjksp} \text{kanjiskip\_natural, kanjiskip\_stretch, kanjiskip\_shrink keys (Page ??) makes the Lua\TeX-ja inserts not only a glue which is specified by a JFM, and also the natural width/stretch part/shrink part of \texttt{kanjiskip}.}

This functionality is disabled by \texttt{-ltjksp} specification.

1 \texttt{\leavevmode}
2 \texttt{\ltjsetparameter\{kanjiskip=0pt plus 3\zw\}}
3 \texttt{\vrule\hbox to 15\zw{あ「い」う, えお}\vrule\}
4 \texttt{\jfont\G=HaranoAjiMincho-Regular:jfm=ujisv\%}
5 \texttt{\vrule\hbox to 15\zw{あ「い」う, えお}\vrule\}
6 \texttt{\G\leavevmode\%}
7 \texttt{\vrule\hbox to 15\zw{あ「い」う, えお}\vrule}
7.3 Default Japanese fonts and JFMs

If following commands are defined at loading Lua\TeX-ja package, these change default Japanese fonts and JFMs for them:

\texttt{\textbackslash ltj@stdmcfont} The default Japanese font for the mincho family.
\texttt{\textbackslash ltj@stdgtfont} The default Japanese font for the gothic family.
\texttt{\textbackslash ltj@stdyokojfm} The default JFM for horizontal direction.
\texttt{\textbackslash ltj@stdtatejfm} The default JFM for vertical direction.

For example,
\begin{verbatim}
\def\ltj@stdmcfont{IPAMincho}
\def\ltj@stdgtfont{IPAGothic}
\end{verbatim}

makes that IPA Mincho and IPA Gothic will be used as default Japanese fonts, instead of Harano Aji fonts.

This feature is intended for classes which use special JFMs\footnote{This is because commands has @ in their names.}. It is recommended to use \texttt{\textbackslash luatexja-preset} or \texttt{\textbackslash luatexja-fontspec} package to select standard fonts in ordinary \LaTeX sources.

For compatibility with earlier versions, Lua\TeX-ja reads \texttt{luatexja.cfg} automatically if it is found by Lua\TeX. One should not overuse this \texttt{luatexja.cfg}; it will overwrite the definition of \texttt{\textbackslash ltj@stdmcfont} and others.

7.4 Prefix \texttt{psft}

Besides "file" and "name" prefixes which are introduced in the luaotfload package, Lua\TeX-ja adds "psft" prefix in \texttt{jfont} (and \texttt{font}), to specify a "name-only" Japanese font which will not be embedded to PDF. Note that these non-embedded fonts under current Lua\TeX has Identity-H encoding, and this violates the standard ISO32000-1:2008 (\cite{10}).

OpenType font features, such as "+jp90", have no meaning in name-only fonts using "psft" prefix, because we can’t expect what fonts are actually used by the PDF reader. Note that extend and slant settings (see above) are supported with psft prefix, because they are only simple linear transformations.

\textbf{cid key} The default font defined by using psft prefix is for Japanese typesetting; it is Adobe-Japan1-7 CID-keyed font. One can specify cid key to use other CID-keyed non-embedded fonts for Chinese or Korean typesetting.
7.5 Structure of a JFM file

A JFM file is a Lua script which has only one function call:

```lua
luatexja.jfont.define_jfm { ... }
```

Real data are stored in the table which indicated above by `{ ... }`. So, the rest of this subsection are devoted to describe the structure of this table. Note that all lengths in a JFM file are floating-point numbers in design-size unit.

`version=(version)` (optional, default value is 1)

The version JFM. Currently 1, 2, and, 3 are supported

`dir=(direction)` (required)

The direction of JFM. 'yoko' (horizontal) or 'tate' (vertical) are supported.

`zw=(length)` (required)

The amount of the length of the "full-width".

`zh=(length)` (required)

The amount of the "full-height" (height + depth).

`kanjiskip=({natural}, {stretch}, {shrink})` (optional)

This field specifies the "ideal" amount of `kanjiskip`. As noted in Subsection 4.2, if the parameter `kanjiskip` is `\maxdimen`, the value specified in this field is actually used (if this field is not specified in JFM, it is regarded as 0 pt). Note that `{stretch}` and `{shrink}` fields are in design-size unit too.

`xkanjiskip=({natural}, {stretch}, {shrink})` (optional)

Like the `kanjiskip` field, this field specifies the "ideal" amount of `xkanjiskip`. 

i Note that the code above specifies jfm-jis.lua, which is for Japanese fonts, as JFM for Chinese and Korean fonts.

At present, LuaTeX-ja supports only 5 values written in the sample code above. Specifying other values, e.g.,

```lua
\jfont\test= {psft:Ryumin-Light:cid=Adobe-Japan2;jfm=jis}
```

produces the following error:

1 Package luatexja Error: bad cid key 'Adobe-Japan2'.

See the luatexja package documentation for explanation.

Type H <return> for immediate help.
	<to be read again>

I couldn't find any non-embedded font information for the CID
"Adobe-Japan2". For now, I'll use "Adobe-Japan1-6".
Please contact the LuaTeX-ja project team.

?
Consider a Japanese character node which belongs to a character class whose the align field is 'middle'.

- The black rectangle is the imaginary body of the node. Its width, height, and depth are specified by JFM.
- Since the align field is 'middle', the "real" glyph is centered horizontally (the green rectangle) first.
- Furthermore, the glyph is shifted according to values of fields left and down. The ultimate position of the real glyph is indicated by the red rectangle.

**Table 13. Default values of width field and other fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>width field</td>
<td>the width of the &quot;real&quot; glyph</td>
</tr>
<tr>
<td>height field</td>
<td>the height of the &quot;real&quot; glyph</td>
</tr>
<tr>
<td>depth field</td>
<td>the depth of the &quot;real&quot; glyph</td>
</tr>
<tr>
<td>italic field</td>
<td>0.0</td>
</tr>
</tbody>
</table>

| Character classes | Besides from above fields, a JFM file have several sub-tables those indices are natural numbers. The table indexed by $i \in \omega$ stores information of character class $i$. At least, the character class 0 is always present, so each JFM file must have a sub-table whose index is [0]. Each sub-table (its numerical index is denoted by $i$) has the following fields:

- **chars**={⟨character⟩, ...} (required except character class 0)

  This field is a list of characters which are in this character type $i$. This field is optional if $i = 0$, since all JAchar which do not belong any character classes other than 0 are in the character class 0 (hence, the character class 0 contains most of JAchars). In the list, character(s) can be specified in the following form:
  - a Unicode code point
  - the character itself (as a Lua string, like ‘あ’)
  - a string like ‘あ*’ (the character followed by an asterisk)
  - several "imaginary" characters (We will describe these later.)

- **width**=⟨length⟩, **height**=⟨length⟩, **depth**=⟨length⟩, **italic**=⟨length⟩ (required)

  Specify the width of characters in character class $i$, the height, the depth and the amount of italic correction. All characters in character class $i$ are regarded that its width, height, and depth are as values of these fields. The default values are shown in Table 13.

- **left**=⟨length⟩, **down**=⟨length⟩, **align**=⟨align⟩

  These fields are for adjusting the position of the "real" glyph. Legal values of align field are 'left', 'middle', and 'right'. If one of these 3 fields are omitted, left and down are treated as 0, and align field is treated as 'left'. The effects of these 3 fields are indicated in Figure 4 and Figure 5.

  In most cases, left and down fields are 0, while it is not uncommon that the align field is 'middle' or 'right'. For example, setting the align field to 'right' is practically needed when the current character class is the class for opening delimiters'.

- **kern**={[,]=⟨kern⟩, [,′]=⟨kern⟩, [ratio=⟨ratio⟩]}, ...}

- **glue**={[,]=⟨width⟩, ⟨stretch⟩, ⟨shrink⟩, [ratio=⟨ratio⟩], ...]}, ...}

  Specifies the amount of kern or glue which will be inserted between characters in character class $i$ and those in character class $j$. 27
Figure 5. The position of the real glyph (vertical Japanese fonts)

\(\langle \text{ratio} \rangle\) specifies how much the glue is originated in the “right” character. It is a real number between 0 and 1, and treated as 0.5 if omitted. For example, the width of a glue between an ideographic full stop “。 ” and a fullwidth middle dot “・ ” is three-fourths of fullwidth, namely halfwidth from the ideographic full stop, and quarter-width from the fullwidth middle dot. In this case, we specify \(\langle \text{ratio} \rangle\) to \(0.25/(0.5 + 0.25) = 1/3\). In case of glue, one can specify following additional keys in each \([j]\) subtable:

\textbf{priority}=(priority) An integer in \([-4, 3]\) (treated as 0 if omitted), or a pair of these integers \{(stretch), (shrink)\} (version 2 or later). This is used only in line adjustment with priority by \texttt{luatexja-adjust} (see Subsection 11.3). Higher value means the glue is easy to stretch, and is also easy to shrink.

\textbf{kanjiskip_natural}=(num), \textbf{kanjiskip_stretch}=(num), \textbf{kanjiskip_shrink}=(num)

These keys specifies the amount of the natural width of \texttt{kanjiskip} (the stretch/shrink part, respectively) which will be inserted in addition to the original JFM glue. Default values of them are all 0.

As an example, in \texttt{jfm-ujis.lua}, the standard JFM in horizontal writing, we have

- Between an ordinal letter “あ” and an ideographic opening bracket, we have a glue whose natural part and shrink part are both half-width, while its stretch part is zero. However, this glue also can be stretched as much as the stretch part of \texttt{kanjiskip} times the value of \texttt{kanjiskip_stretch} key (1 in this case).
- Between an ideographic closing brackets (the ideographic comma “， ” is included) and an ordinal letter, we have the same glue. Again, this glue also can be stretched as much as the stretch part of \texttt{kanjiskip} times the value of \texttt{kanjiskip_stretch} key (1 in this case).
- Between an ideographic opening bracket and an ordinal letter and between an ordinal letter and an ideographic closing bracket, we have a glue whose natural part and stretch part are both zero, while its shrink part as much as the shrink part of \texttt{kanjiskip}.

Hence we have the following result:

```
\leavevmode
\ltjsetparameter{kanjiskip=0pt plus 3zw}
\vrule\hbox to 15zw{あ「い」う，えお}\vrule
\vrule\hbox{あ「い」う，えお}\vrule\par
\ltjsetparameter{kanjiskip=0pt minus \zw}
\vrule\hbox to 6.5\zw{あ「い」う，えお}\vrule
end_stretch=(kern), end_shrink=(kern) (optional, version 1 only)
end_adjust={(kern), (kern), ...} (optional, version 2 or later)
```

\textbf{Character to character classes} We explain how the character class of a character is determined, using \texttt{jfm-test.lua} which contains the following:
Now consider the following input/output:

```
\jfont{IPAexMincho:jfm=test;+hwid} \setbox0\hbox{\a

漢

ヒ}
\the\wd0

15.0pt
```

Now we look why the above source outputs 15 pt.

1. The character “ヒ” is converted to its half width form “ヒ” by hwid feature.
2. According to the JFM, the character class of “ヒ” is 2000, hence its width is halfwidth.
3. The character class of “漢” is zero, hence its width is fullwidth.
4. Hence the width of \hbox equals to 15 pt.

This example shows that the character class of a character is generally determined after applying font features by luaotfload.

However, if the class determined by the glyph after application of features is zero, LuaTeX-ja adopts the class determined by the glyph before application of features. The following input is an example.

```
\jfont{HaranoAjiMincho-Regular:jfm=test;+vert} \a

漢。
\inhibitglue

漢

漢︒ 漢
```

Here, the character class of the ideographic full stop “。” (U+3002) is determined as follows:

1. As the case of “ヒ”, the ideographic full stop “。” is converted to its vertical form “︒” (U+FE12) by vert feature.
2. The character class of “︒”, according to the JFM is zero.
3. However, LuaTeX-ja remembers that this “︒” is obtained from “。” by font features. The character class of “。” is non-zero value, namely, 2000.
4. Hence the ideographic full stop “。” in above belongs the character class 2000.

**Imaginary characters** As described before, you can specify several “imaginary characters” in chars field. The most of these characters are regarded as the characters of class 0 in \TeX. As a result, LuaTeX-ja can control typesetting finer than \TeX. The following is the list of imaginary characters:

- `boxbdd`
  The beginning/ending of a hbox, and the beginning of a noindented (i.e., began by `\noindent`) paragraph. If a hbox $b$ begins (resp. ends) a glue or kern between this “character” and a JAchar, JAglue won’t be inserted before(resp. after) the hbox $b$. `kanjiskip` and `xkanjiskip` around a hbox.

- `parbdd`
  The beginning of an (indented) paragraph.

- `jcharbdd`
  A boundary between JAchar and anything else.

- `alchar`, `nox_alchar`
  (version 3 or later) A boundary between JAchar and ALchar.

- `glue`
  (version 3 or later) A boundary between JAchar, and, a glue or kern.

- `−1`
  The left/right boundary of an inline math formula.
Table 14. Commands for Japanese math fonts

<table>
<thead>
<tr>
<th>Japanese fonts</th>
<th>alphabetic fonts</th>
</tr>
</thead>
<tbody>
<tr>
<td>\jfam ∈ [0, 256)</td>
<td>\fam</td>
</tr>
<tr>
<td>\jatextfont ={\jfam, (jfont_cs)}</td>
<td>\textfont(\fam)=(\font_cs)</td>

<tr>
<td>\jascriptscriptfont ={\jfam, (jfont_cs)}</td>
<td>\scriptscriptfont(\fam)=(\font_cs)</td>
</tr>
</tbody>
</table>

Porting JFM from \(\mathtt{p\TeX}\)  See Japanese version of this manual.

7.6 Math font family

\(\mathtt{\TeX}\) handles fonts in math formulas by 16 font families\(^{10}\), and each family has three fonts: \textfont, \scriptfont and \scriptscriptfont.

Lua\(\mathtt{\TeX}\)-ja’s handling of Japanese fonts in math formulas is similar; Table 14 shows counterparts to \(\mathtt{\TeX}\)’s primitives for math font families. There is no relation between the value of \fam and that of \jfam; with appropriate settings, you can set both \fam and \jfam to the same value. Here (jfont_cs) in the argument of \jatextfont etc. is a control sequence which is defined by \jfont, i.e., a horizontal Japanese font.

7.7 Callbacks

Lua\(\mathtt{\TeX}\)-ja also has several callbacks. These callbacks can be accessed via \texttt{luatexbase.add_to_callback} function and so on, as other callbacks.

\texttt{luatexja.load_jfm} callback

With this callback you can overwrite JFMs. This callback is called when a new JFM is loaded.

\begin{verbatim}
function (table jfm_info, string jfm_name)
  return table new_jfm_info
end
\end{verbatim}

The argument jfm_info contains a table similar to the table in a JFM file, except this argument has \texttt{chars} field which contains character codes whose character class is not 0.

An example of this callback is the \texttt{ltjarticle} class, with forcefully assigning character class 0 to 'parbdd' in the JFM \texttt{jfm-min.lua}.

\texttt{luatexja.define_jfont} callback

This callback and the next callback form a pair, and you can assign characters which do not have fixed code points in Unicode to non-zero character classes. This \texttt{luatexja.define_font} callback is called just when new Japanese font is loaded.

\begin{verbatim}
function (table jfont_info, number font_number)
  return table new_jfont_info
end
\end{verbatim}

\texttt{jfont_info} has the following fields, which may not overwritten by a user:

\texttt{size} The font size specified at \jfont in scaled points (1 sp = 2\(^{-16}\) pt).

\texttt{zw, zh, kanjiskip, xkanjiskip} These are scaled value of those specified by the JFM, by the font size.

\texttt{jfm} The internal number of the JFM.

\texttt{var} The value of jfmvar key, which is specified at \jfont. The default value is the empty string.

\texttt{chars} The mapping table from character codes to its character classes.

The specification \texttt{[i].chars={\langle character\rangle, \ldots}} in the JFM will be stored in this field as \texttt{chars={\langle character\rangle=i, \ldots}}.

\(^{10}\)\(\Omega\), \(\aleph\), Lua\(\mathtt{\TeX}\) and \(\varepsilon\)-(u)p\(\mathtt{\TeX}\) can handles 256 families, but an external package is needed to support this in plain \(\mathtt{\TeX}\) and \(\mathtt{\LaTeX}\).
char_type For \( i \in \omega \), char_type[\( i \)] is information of characters whose class is \( i \), and has the following fields:

- width, height, depth, italic, down, left are just scaled value of those specified by the JFM, by the font size.
- align is a number which is determined from align field in the JFM:
  \[
  \begin{cases}
  1 & \text{('right' in JFM)}, \\
  0.5 & \text{('middle' in JFM)}, \\
  0 & \text{otherwise}.
  \end{cases}
  \]

For \( i, j \in \omega \), char_type[\( i \)][\( j \)] stores a kern or a glue which will be inserted between character class \( i \) and class \( j \).

The returned table new_jfont_info also should include these fields, but you are free to add more fields (to use them in the luatexja.find_char_class callback). The font_number is a font number.

A good example of this and the next callbacks is the luatexja-off package, supporting "AJ1-xxx" form for Adobe-Japan1 CID characters in a JFM. This callback doesn't replace any code of LuaTeX-ja.

luatexja.find_char_class callback

This callback is called just when LuaTeX-ja is trying to determine which character class a character chr_code belongs. A function used in this callback should be in the following form:

\begin{verbatim}
function (number char_class, <table> jfont_info, <number> chr_code)
if char_class~=0 then return char_class
else 
   ....
return (<number> new_char_class or 0)
end
end
\end{verbatim}

The argument char_class is the result of LuaTeX-ja's default routine or previous function calls in this callback, hence this argument may not be 0. Moreover, the returned new_char_class should be as same as char_class when char_class is not 0, otherwise you will overwrite the LuaTeX-ja's default routine.

luatexja.set_width callback

This callback is called when LuaTeX-ja is trying to encapsule a JAchar glyph_node, to adjust its dimension and position.

\begin{verbatim}
function (<table> shift_info, <table> jfont_info, <table> char_type)
return <table> new_shift_info
end
\end{verbatim}

The argument shift_info and the returned new_shift_info have down and left fields, which are the amount of shifting down/left the character in a scaled point.

A good example is test/valign.lua. After loading this file, the vertical position of glyphs is automatically adjusted; the ratio \((\text{height} : \text{depth})\) of glyphs is adjusted to be that of letters in the character class 0. For example, suppose that

- The setting of the JFM: \((\text{height}) = 88x, (\text{depth}) = 12x\) (the standard values of Japanese OpenType fonts);
- The value of the real font: \((\text{height}) = 28y, (\text{depth}) = 5y\) (the standard values of Japanese TrueType fonts).

Then, the position of glyphs is shifted up by

\[
\frac{88x}{88x + 12x} \cdot (28y + 5y) - 28y = \frac{26}{25} y = 1.04y.
\]
8 Parameters

8.1 \ltjsetparameter

As described before, \ltjsetparameter and \ltjgetparameter are commands for accessing most parameters of LuaTeX-ja. One of the main reason that LuaTeX-ja didn’t adopted the syntax similar to that of pTeX (e.g., \prebreakpenalty = 10000) is the position of hpack_filter callback in the source of LuaTeX, see Section 12.

\ltjsetparameter and \ltjglobalsetparameter are commands for assigning parameters. These take one argument which is a key-value list. The difference between these two commands is the scope of assignment; \ltjsetparameter does a local assignment and \ltjglobalsetparameter does a global one by default. They also obey the value of \globaldefs, like other assignments.

The following is the list of parameters which can be specified by the \ltjsetparameter command. \cs indicates the counterpart in pTeX, and symbols beside each parameter has the following meaning:

• “∗” : values at the end of a paragraph or a hbox are adopted in the whole paragraph or the whole hbox.
• “†” : assignments are always global.

\texttt{jcharwidowpenalty=(penalty)* [jcharwidowpenalty]}

Penalty value for suppressing orphans. This penalty is inserted just after the last JAchar which is not regarded as a (Japanese) punctuation mark.

\texttt{kcatcode=\{(chr_code),(natural number)\}† [kcatcode]}

An additional attributes which each character whose character code is \langle chr_code \rangle has. At version 20120506.0 or later, the lowermost bit of \langle natural number \rangle indicates whether the character is considered as a punctuation mark (see the description of \texttt{jcharwidowpenalty} above).

\texttt{prebreakpenalty=\{(chr_code),(penalty)\}† [prebreakpenalty]}

Set a penalty which is inserted automatically before the character \langle chr_code \rangle, to prevent a line starts from this character. For example, a line cannot started with one of closing brackets “] ”, so LuaTeX-ja sets
\texttt{\ltjsetparameter{prebreakpenalty={`]},10000}}

by default.

pTeX has following restrictions on \prebreakpenalty and \postbreakpenalty, but they don’t exist in LuaTeX-ja:

• Both \prebreakpenalty and \postbreakpenalty cannot be set for the same character.
• We can set \prebreakpenalty and \postbreakpenalty up to 256 characters.

\texttt{postbreakpenalty=\{(chr_code),(penalty)\}† [postbreakpenalty]}

Set a penalty which is inserted automatically after the character \langle chr_code \rangle, to prevent a line ends with this character.

\texttt{jatextfont=\{(jfam),(jfont_cs)\}† [textfont in TeX]}

\texttt{jascriptfont=\{(jfam),(jfont_cs)\}† [scriptfont in TeX]}

\texttt{jascriptscriptfont=\{(jfam),(jfont_cs)\}† [scriptscriptfont in TeX]}

\texttt{yjabaselineshift=(dimen) [ybaselineshift]}

\texttt{valbaselineshift=(dimen) [ybaselineshift]}

\texttt{tjabaselineshift=(dimen) [tbaselineshift]}

\texttt{talbaselineshift=(dimen) [tbaselineshift]}

32
\texttt{jaxspmode} = \{(\texttt{chr\_code}), (\texttt{mode})\}^* \\
Set whether inserting \texttt{xkanjiskip} is allowed before/after a \texttt{JAchar} whose character code is \texttt{chr\_code}. The followings are allowed for \texttt{(mode)}:

0, \texttt{inhibit} Insertion of \texttt{xkanjiskip} is inhibited before the character, nor after the character.
1, \texttt{preonly} Insertion of \texttt{xkanjiskip} is allowed before the character, but not after.
2, \texttt{postonly} Insertion of \texttt{xkanjiskip} is allowed after the character, but not before.
3, \texttt{allow} Insertion of \texttt{xkanjiskip} is allowed both before the character and after the character. This is the default value.

This parameter is similar to the \texttt{\inhibitxspcode} primitive of \LaTeX, but not compatible with \texttt{\inhibitxspcode}.

\texttt{alxspmode} = \{(\texttt{chr\_code}), (\texttt{mode})\}^* [\texttt{xspcode}]
\begin{itemize}
  \item 0, \texttt{inhibit} Insertion of \texttt{xkanjiskip} is inhibited before the character, nor after the character.
  \item 1, \texttt{preonly} Insertion of \texttt{xkanjiskip} is allowed before the character, but not after.
  \item 2, \texttt{postonly} Insertion of \texttt{xkanjiskip} is allowed after the character, but not before.
  \item 3, \texttt{allow} Insertion of \texttt{xkanjiskip} is allowed both before the character and after the character. This is the default value.
\end{itemize}

Note that parameters \texttt{jaxspmode} and \texttt{alxspmode} share a common table, hence these two parameters are synonyms of each other.

\texttt{autospacing} = (\texttt{bool}) [\texttt{autospacing}]
\texttt{autoxspacing} = (\texttt{bool}) [\texttt{autoxspacing}]
\texttt{kanjiskip} = (\texttt{skip})^* [\texttt{kanjiskip}]
\begin{itemize}
  \item The default glue which inserted between two \texttt{JAchar}s. Changing current Japanese font does not alter this parameter, as \LaTeX.
  \item If the natural width of this parameter is \texttt{maxdimen}, Lua\TeX-ja uses the value which is specified in the JFM for current Japanese font (See Subsection 7.5).
\end{itemize}

\texttt{xkanjiskip} = (\texttt{skip})^* [\texttt{xkanjiskip}]
\begin{itemize}
  \item The default glue which inserted between a \texttt{JAchar} and an \texttt{ALchar}. Changing current font does not alter this parameter, as \LaTeX.
  \item As \texttt{kanjiskip}, if the natural width of this parameter is \texttt{maxdimen}, Lua\TeX-ja uses the value which is specified in the JFM for current Japanese font (See Subsection 7.5).
\end{itemize}

\texttt{differentjfm} = (\texttt{mode})
\begin{itemize}
  \item Specify how glues/kerns between two \texttt{JAchar}s whose JFM (or size) are different. The allowed arguments are the followings:
    \begin{itemize}
      \item average, both, large, small, pleft, pright, paverage
    \end{itemize}
  \item The default value is \texttt{paverage}.
\end{itemize}

\texttt{jacharrange} = (\texttt{ranges})
\texttt{kansujichar} = \{(\texttt{digit}), (\texttt{chr\_code})\}^* [\texttt{kansujichar}]
\texttt{direction} = (\texttt{dir}) (always local)
\begin{itemize}
  \item Assigning to this parameter has the same effect as \texttt{\yoko} (if \texttt{dir} = 4), \texttt{\tate} (if \texttt{dir} = 3), \texttt{\dtou} (if \texttt{dir} = 1) or \texttt{\utod} (if \texttt{dir} = 11). If the argument \texttt{dir} is not one of 4, 3, 1 nor 11, the behavior of this assignment is undefined.
\end{itemize}
8.2 \ltjgetparameter

\ltjgetparameter is a control sequence for acquiring parameters. It always takes a parameter name as first argument.

\begin{verbatim}
\ltjgetparameter{differentjfm},
\ltjgetparameter{autospacing},
\ltjgetparameter{kanjiskip},
\ltjgetparameter{prebreakpenalty}\{\}
\end{verbatim}

The return value of \ltjgetparameter is always a string, which is outputted by \texttt{text.write()}. Hence any character other than space " " (U+0020) has the category code 12 (other), while the space has 10 (space).

- If first argument is one of the following, no additional argument is needed.
  jcharwidownpenalty, yjabaselineshift, yalbaselineshift, autospacing, autoxspacing,
  kanjiskip, xkanjiskip, differentjfm, direction

Note that \ltjgetparameter{autospacing} and \ltjgetparameter{autoxspacing} returns 1 or 0, not true nor false.

- If first argument is one of the following, an additional argument—a character code, for example—is needed.
  kcatcode, prebreakpenalty, postbreakpenalty, jaxspmode, alxspmode

\ltjgetparameter{jaxspmode}{...} and \ltjgetparameter{alxspmode}{...} returns 0, 1, 2, or 3, instead of preonly etc.

- For an integer \langle digit \rangle between 0 and 9, \ltjgetparameter{kansujichar}\{\langle digit \rangle\} returns the character code of the result of \kansuji\langle digit \rangle).

- \ltjgetparameter{adjustdir} returns a integer which represents the direction of the surrounding vertical list. As direction, the return value 1 means down-to-up direction, 3 means tate direction (vertical typesetting), and 4 means yoko direction (horizontal typesetting).

- For an integer \langle reg_num \rangle between 0 and 65535, \ltjgetparameter{boxdim}\{\langle reg_num \rangle\} returns the direction of \box\langle reg_num \rangle. If this box register is void, the returned value is zero.

- The following parameter names cannot be specified in \ltjgetparameter.
  jatextfont, jascriptfont, jascriptscriptfont, jacharrange

- \ltjgetparameter{chartorange}\{\langle chr_code \rangle\} returns the range number which \langle chr_code \rangle belongs to (although there is no parameter named "chartorange").

  If \langle chr_code \rangle is between 0 and 127, this \langle chr_code \rangle does not belong to any character range. In this case, \ltjgetparameter{chartorange}\{\langle chr_code \rangle\} returns −1.

  Hence, one can know whether \langle chr_code \rangle is JChar or not by the following:

\begin{verbatim}
\ltjgetparameter{jacharrange}\{\ltjgetparameter{chartorange}\{\langle chr_code \rangle\}\}
\end{verbatim}

% 0 if JChar, 1 if ALChar

- Because the returned value is string, the following conditionals do not work if kanjiskip (or xkanjiskip) has the stretch part or the shrink part.

\begin{verbatim}
\ifdim\ltjgetparameter{kanjiskip}>\z@ ... \fi
\ifdim\ltjgetparameter{xkanjiskip}>\z@ ... \fi
\end{verbatim}

The correct way is using a temporary register.

\begin{verbatim}
@tempskipa=\ltjgetparameter{kanjiskip}\ifdim@tempskipa>\z@ ... \fi
@tempskipa=\ltjgetparameter{xkanjiskip}\ifdim@tempskipa>\z@ ... \fi
\end{verbatim}

34
8.3 Alternative Commands to \ltjsetparameter

The basic method to set parameters of Lua\TeX\-ja is to use \ltjsetparameter or \ltjglobalsetparameter. However, these commands are slow, because they parse a key-value list, so several alternative commands are used in Lua\TeX\-ja. This subsection is not for general Lua\TeX\-ja users.

### Setting \texttt{kanjiskip} or \texttt{xkanjiskip}

In \texttt{ltjsclasses}, every size-changing command such as \Large changes \texttt{kanjiskip} and \texttt{xkanjiskip}. But a simple implementation, as the code below, is slow since two key-value lists are parsed by \ltjsetparameter:

\begin{verbatim}
\ltjsetparameter{kanjiskip=0\zw plus .1\zw minus .01\zw}
@tempskipa=\ltjgetparameter{xkanjiskip}
ifdim@tempskipa>\z@
  \if@slide
    \ltjsetparameter{xkanjiskip=0.1em}
  \else
    \ltjsetparameter{xkanjiskip=0.25em plus 0.15em minus 0.06em}
  fi
fi
\end{verbatim}

Hence, Lua\TeX\-ja defines more primitive commands, namely \ltj@setpar@global, \ltjsetkanjiskip, and \ltjsetxkanjiskip. Here

\begin{verbatim}
\ltj@setpar@global\ltjsetkanjiskip 10pt
\end{verbatim}

and \ltjsetparameter{kanjiskip=10pt} has the same effect. The actual code of \texttt{ltjsclasses} is shown below:

\begin{verbatim}
\ltjsetparameter{kanjiskip=0\zw plus .1\zw minus .01\zw}
@tempskipa=\ltjgetparameter{xkanjiskip}
ifdim@tempskipa>\z@
  \if@slide
    \ltjsetxkanjiskip.1em
  \else
    \ltjsetxkanjiskip.25em plus 0.15em minus 0.06em
  fi
fi
\end{verbatim}

Note that using \ltjsetkanjiskip or \ltjsetxkanjiskip alone, that is, without executing \ltj@setpar@global in advance, is not supported.

9 Other Commands for \texttt{plain \TeX} and \texttt{\LaTeX\,2\epsilon}

9.1 Commands for compatibility with \texttt{p\LaTeX}

The following commands are implemented for compatibility with \texttt{p\LaTeX}. Note that the former five commands don’t support JIS X 0213, but only JIS X 0208. The last \texttt{\kansuji} converts an integer into its Chinese numerals.

\begin{verbatim}
\kuten, \jis, \euc, \sjis, \ucs, \kansuji
\end{verbatim}

These six commands takes an internal integer, and returns a string.

\begin{verbatim}
\newcount\hoge
\hoge=\string{2423 %}
@the\hoge, \kansuji\hoge\}
@jis\hoge, \char\jis\hoge\}
\kansuji1701
\end{verbatim}

To change characters of Chinese numerals for each digit, set \texttt{\kansujichar} parameter:

\begin{verbatim}
\ltjsetparameter{\kansujichar={1,`壹}}
\ltjsetparameter{\kansujichar={7,`漆}}
\ltjsetparameter{\kansujichar={0,`零}}
\kansuji1701
\end{verbatim}

35
9.2 \inhibitglue

\inhibitglue suppresses the insertion of JAglue. The following is an example, using a special JFM that there will be a glue between the beginning of a box and “あ”, and also between “あ” and “ウ”.

\begin{verbatim}
\lfont=HaranoAjiMincho-Regular:jfm=test \g
\inbox{\hbox{あウあ\inhibitglue ウ}}
\inhibitglue\par\noindent あ
\inhibitglue\noindent あ
\inhibitglue\hrule
\inhibitglue ice
\end{verbatim}

With the help of this example, we remark the specification of \inhibitglue:

- The call of \inhibitglue in the (internal) vertical mode is simply ignored.
- The call of \inhibitglue in the (restricted) horizontal mode is only effective on the spot; does not get over boundary of paragraphs. Moreover, \inhibitglue cancels ligatures and kernings, as shown in the last line of above example.
- The call of \inhibitglue in math mode is just ignored.

9.3 \ltjfakeboxbdd, \ltjfakeparbegin

Sometimes ‘parbdd’ and ‘boxbdd’ specifications look like “fail”, especially in paragraphs inside list environments. This is because \everypar inserts some nodes such as boxes and kerns, so the “first letter” in a paragraph is in fact not the first letter.

\begin{verbatim}
\parindent1\zw
\noindent ああああああああ\par % for comparison ああああああああ
「あああああ\par % normal paragraph ああああああああ
\everypar{\null}
「ああああああ
\ltjfakeboxbdd and \ltjfakeparbegin primitives resolve this situation.

- \ltjfakeparbegin creates a node which indicates “beginning of an indented paragraph” to the insertion process of JAglue.
- \ltjfakeboxbdd creates a node which indicates “beginning/ending of a box” to the insertion process of JAglue.

As an example, the example above can be improved as follows:

\begin{verbatim}
\parindent1\zw
\noindent ああああああああ\par % for comparison ああああああああ
「あああああ\par % normal paragraph ああああああああ
\everypar{\null}{\ltjfakeparbegin}
「ああああああ
\end{verbatim}

9.4 \ltjdeclarealtfont

Using \ltjdeclarealtfont, one can "compose" more than one Japanese fonts. This \ltjdeclarealtfont uses in the following form:

\begin{verbatim}
\ltjdeclarealtfont{base_font_cs}{alt_font_cs}{(range)}
\end{verbatim}

where (base_font_cs) and (alt_font_cs) are defined by \lfont. Its meaning is

- If the current Japanese font is (base_font_cs), characters which belong to (range) is typeset by another Japanese font (alt_font_cs), instead of (base_font_cs).
Here (range) is a comma-separated list of character codes, but also accepts negative integers: \(-n\) \((n \geq 1)\) means that all characters of character classes \(n\), with respect to JFM used by ⟨base_font cs⟩. Note that characters which do not exist in ⟨alt_font cs⟩ are ignored.

For example, if \(\text{\textbackslash hoge}\) uses jfm-ujis.lua, the standard JFM of Lua\TeX-ja, then
\[
\ltjdeclarealtfont\hoge\piyo("3000-"30FF, \{-1\}-\{-1\})
\]
does

If the current Japanese font is \(\text{\textbackslash hoge}\), U+3000–U+30FF and characters in class 1 (ideographic opening brackets) are typeset by \(\text{\textbackslash piyo}\).

Note that specifying negative numbers needs specification like \{-1\}-\{-1\}, because simple \"-1\" is treated as the range between 0 and 1.

\begin{verbatim}
\gtfamily\large
\&,\char`\&\&,\ltjalchar`\&\&,\ltjjachar`\&\& % default: Alchar
\#,\char`\#\&,\ltjalchar`\#\&,\ltjjachar`\#\& % default: JAcchar
\%,\char`\%\&,\ltjalchar`\%\&,\ltjjachar`\%\& % JAcchar unless \ltjjachar
\end{verbatim}

10 Commands for \LaTeX{}\(\varepsilon\)

10.1 Loading Japanese fonts in \LaTeX{}\(\varepsilon\)

From version 20190107, Lua\TeX-ja does not load Japanese fonts for horizontal direction and that for vertical direction at same time to reduce the number of loaded fonts. This will save time for typesetting and memory consumption of Lua side ([11]).

- \selectfont loads (and chooses) only the Japanese font for current direction, and does not load the Japanese font for other direction (Lua\TeX-ja only detects its size and JFM, to calculate the amount of shifting the baseline).

- Direction changing commands (\yoko, \tate, \dtou, \utod) are patched to include the following process:
  
  If the Japanese font for new direction is not loaded, Lua\TeX-ja loads it automatically.

  Original commands are saved as \ltj@@orig@yoko etc.

- Specifying Japanese font command which is defined by \jfont, \tfont, or \DeclareFixedFont directly actually loads (and selects) the Japanese font. For example, \texttt{\textbackslash JAcchar in \box0} will be typeset in \HOGE, in the following code:

\begin{verbatim}
% in horizontal direction \yoko
\DeclareFixedFont\HOG{JT3}{lt}{m}{n}\{12\} % JT3: for vertical direction
\HOGE
\setbox0=\hbox{\tate \=\im}\end{verbatim}

10.2 Patch for NFSS2

Japanese patch for NFSS2 in Lua\TeX-ja is based on \texttt{plfonts.dtx} which plays the same role in \LaTeX{}\(\varepsilon\). We will describe commands which are not described in Subsection 3.1.

additional dimensions

Like \texttt{plfonts.dtx}, Lua\TeX-ja defines the following dimensions for information of current Japanese font:

\begin{verbatim}
\cht (height), \cdp (depth), \cHT (sum of former two),
\cwd (width), \cvs (lineskip), \chs (equals to \cwd)
\end{verbatim}

and its \texttt{\normalsize} version:
\texttt{cht (height), \texttt{cdp (depth), \texttt{cw} (width),}
\texttt{cvs (equals to \texttt{baselineskip}), \texttt{chs (equals to \texttt{cw}).}}

Note that \texttt{cw} and \texttt{cHT} may differ from \texttt{zw} and \texttt{zh} respectively. On the one hand the former dimensions are determined from a character whose character class is zero, but on the other hand \texttt{zw} and \texttt{zh} are specified by JFM.

\texttt{DECLAREYOKOKANJIENCODING}{\texttt{encoding}}{\texttt{text-settings}}{\texttt{math-settings}}
\texttt{DECLARETATEKANJIENCODING}{\texttt{encoding}}{\texttt{text-settings}}{\texttt{math-settings}}

In NFSS2 under Lua\TeX{}-ja, distinction between alphabetic fonts and Japanese fonts are only made by their encodings. For example, encodings OT1 and T1 are encodings for alphabetic fonts, and Japanese fonts cannot have these encodings. These command define a new encoding scheme for Japanese font families.

\texttt{DECLAREKANJIENCODINGDEFAULTS}{\texttt{text-settings}}{\texttt{math-settings}}
\texttt{DECLAREKANJISUBSTITUTION}{\texttt{encoding}}{\texttt{family}}{\texttt{series}}{\texttt{shape}}
\texttt{DECLAREERRORKANJIFONT}{\texttt{encoding}}{\texttt{family}}{\texttt{series}}{\texttt{shape}}{\texttt{size}}

The above 3 commands are just the counterparts for \texttt{DECLAREFONTENCODINGDEFAULTS} and others.

\texttt{REDECLAREMATHALPHABET}{\texttt{unified-cmd}}{\texttt{al-cmd}}{\texttt{ja-cmd}}

\texttt{DECLAreludeATIONFONT}{\texttt{ja-encoding}}{\texttt{ja-family}}{\texttt{ja-series}}{\texttt{ja-shape}}
\{\texttt{al-encoding}}{\texttt{al-family}}{\texttt{al-series}}{\texttt{al-shape}}\}

This command sets the “accompanied” alphabetic font (given by the latter 4 arguments) with respect to a Japanese font given by the former 4 arguments.

\texttt{SETRELATIONFONT}

This command is almost same as \texttt{DECLAreludeATIONFONT}, except that this command does a local assignment, where \texttt{DECLAreludeATIONFONT} does a global assignment.

\texttt{USERELFONT}

(Only) at the next call of \texttt{selectfont}, change current alphabetic font encoding/family/... to the 'accompanied' alphabetic font family with respect to current Japanese font family, which was set by \texttt{DECLAreludeATIONFONT} or \texttt{SETRELATIONFONT}.

The following is an example of \texttt{SETRELATIONFONT} and \texttt{USERELFONT}:

\begin{verbatim}
1 \makeatletter
2 \SetRelationFont{JY3}{\k@family}{m}{n}{TU}{lmss}{m}{n}
3 % \k@family: currentJapanese font family
4 \userelfont\selectfont あいう abc
\end{verbatim}

\texttt{ADJUSTBASELINE}

In p\TeX{} 2\epsilon, \texttt{ADJUSTBASELINE} sets \texttt{baselineskip} to match the vertical center of “M” and that of “漢” in vertical typesetting:

\[
\texttt{baselineskip} \leftarrow \frac{(h_M + d_M) - (h_\mbox{\tiny 漢} + d_\mbox{\tiny 漢})}{2} + d_{\mbox{\tiny 漢}} - d_M.
\]

where \texttt{h_M} and \texttt{d_M} denote the height of “a” and the depth, respectively. In Lua\TeX{}-ja, this \texttt{ADJUSTBASELINE} does similar task, namely setting the \texttt{talbaselineshift} parameter (a Japanese character whose character class is zero is used, instead of “漢”).

\texttt{FONTFAMILY}{\texttt{family}}

As in \TeX{} 2\epsilon, this command changes current font family (alphabetic, Japanese, or both) to \texttt{family}. See Subsection 10.3 for detail.

\texttt{FONTSHAPE}{\texttt{shape}}, \texttt{FONTSHAPEFORCE}{\texttt{shape}}

As in \TeX{} 2\epsilon, this command changes current alphabetic font shape according to shape change rules. Traditionally, \texttt{FONTSHAPE} changes also current Japanese font shape always. However, this leads a lot of \TeX{} font warning like.
日本国民は、正当に選挙された国会における代表者を通じて行動し、……

Figure 6. An example of \DeclareAlternateKanjiFont

Font shape `JY3/mc/m/it' undefined
using `JY3/mc/m/n' instead on ....

when \itshape is called, because almost all Japanese fonts only have shape "n", and \itshape calls \fontshape.
LuaTeX-ja 20200323.0 change the behavior. Namely, \fontshape{(shape)} and \fontshapeforce{(shape)}
change current Japanese font shape, only if the required shape (according to shape changing rules)
or (shape) is available in current Japanese font family/series. When this is not the case, an info such as

Kanji font shape JY3/mc/m/it' undefined
No change on ...

is issued instead of a warning.
\kanjishape{(shape)}, \kanjishapeforce{(shape)}
\kanjishape{(shape)} changes current Japanese font shape according to shape change rules, and
\kanjishapeforce{(shape)} changes current Japanese font shape to (shape), regardless of the rules.
Hence \kanjishape{it} produces a warning

Font shape `JY3/mc/m/it' undefined
using `JY3/mc/m/n' instead on ....

which is not produced by \fontshape{it}.

As \ltjdeclarealtfont (Subsection 9.4), characters in (range) of the Japanese font (we say the base font) which specified by first 4 arguments are typeset by the Japanese font which specified by fifth to eighth arguments (we say the alternate font). An example is shown in Figure 6.

Furthermore, LuaTeX-ja applies patches which enables NFSS2 commands, such as \DeclareSymbolFont and \SetSymbolFont, to specify Japanese fonts as math fonts.
Specifying disablejfname option in \usepackage prevents applying these patches. Hence one cannot write Japanese Characters in math mode directly if disablejfname option is specified. The code below does not work either:

\DeclareSymbolFont{mincho}{JY3}{mc}{m}{n}
\DeclareSymbolFontAlphabet{\mathmc}{mincho}
10.3 Detail of \texttt{\fontfamily{family}} command

In this subsection, we describe when $\texttt{\fontfamily{family}}$ changes current Japanese/alphabetic font family. Basically, current Japanese font family is changed to (family) if it is recognized as a Japanese font family, and similar with alphabetic font family. There is a case that current Japanese/alphabetic font family are both changed to (family), and another case that (family) isn’t recognized as a Japanese/alphabetic font family either.

\textbf{Recognition as Japanese font family}  First, Whether Japanese font family will be changed is determined in following order. This order is very similar to $\texttt{\fontfamily{family}}$ in p\LaTeX\ 2e, but we re-implemented in Lua. We use an auxiliary list $N_j$.

1. If the family (family) has been defined already by $\texttt{\DeclareKanjiFamily}$, (family) is recognized as a Japanese font family. Note that (family) need not be defined under current Japanese font encoding.

2. If the family (family) has been listed in a list $N_j$, this means that (family) is not a Japanese font family.

3. If the luatexja-fontspec package is loaded, we stop here, and (family) is not recognized as a Japanese font family.

If the luatexja-fontspec package is not loaded, now Lua\TeX-ja looks whether there exists a Japanese font encoding (enc) such that a font definition named (enc)/(family).fd (the file name is all lowercase) exists. If so, (family) is recognized as a Japanese font family (the font definition file won’t be loaded here). If not, (family) is not a Japanese font family, and (family) is appended to the list $N_j$.

\textbf{Recognition as alphabetic font family}  Next, whether alphabetic font family will be changed is determined in following order. We use auxiliary lists $F_A$ and $N_A$.

1. If the family (family) has been listed in a list $F_A$, (family) is recognized as an alphabetic font family.

2. If the family (family) has been listed in a list $N_A$, this means that (family) is not an alphabetic font family.

3. If there exists an alphabetic font encoding such that the family (family) has been defined under it, (family) is recognized as an alphabetic font family, and to memorize this, (family) is appended to the list $F_A$.

4. Now Lua\TeX-ja looks whether there exists an alphabetic font encoding (enc) such that a font definition named (enc)/(family).fd (the file name is all lowercase) exists. If so, current alphabetic font family will be changed to (family) (the font definition file won’t be loaded here). If not, current alphabetic font family won’t be changed, and (family) is appended to the list $N_A$.

Also, each call of $\texttt{\DeclareFontFamily}$ after loading of Lua\TeX-ja makes the second argument (family) is appended to the list $F_A$.

The above order is very similar to $\texttt{\fontfamily{family}}$ in p\LaTeX\ 2e, but more complicated (clause 3.). This is because p\LaTeX\ 2e is a \textit{format} however Lua\TeX-ja is not, hence Lua\TeX-ja does not know calls of $\texttt{\DeclareFontFamily}$ before itself is loaded.

\textbf{Remarks}  Of course, there is a case that (family) is not recognized as a Japanese font family, nor an alphabetic font family. In this case, Lua\TeX-ja treats "the argument (family) is wrong", so set both current alphabetic and Japanese font family to (family), to use the default family for font substitution.

10.4 Notes on $\texttt{\DeclareTextSymbol}$

From \LaTeX\ 2017/01/01, the standard encoding of Lua\TeX is changed to the TU encoding. This menas that symbols defined by T1 and TS1 encodings can be used without loading any package. To produces these symbols in alphabetic fonts in Lua\TeX-ja, Lua\TeX-ja patches $\texttt{\DeclareTextSymbol}$, and reloads tuenc.def.

Under original definition of $\texttt{\DeclareTextSymbol}$, internal commands which is defined by $\texttt{\DeclareTextSymbol}$ (such as \texttt{$\textnormal{T1}$\texttt{\textquoteright\texttt{left}}}) are \textit{chardef} tokens. However, this no longer holds in Lua\TeX-ja; for example, the meaning of \texttt{$\textnormal{TU}$\texttt{\textquoteright\texttt{left}} is $\texttt{\ltjalchar8220}$.

\addjfontfeatures{Color=00AF00}
\hbox{\yoko 横組}\hbox{\tate 縦組}
\end{verbatim}

Figure 7. An example of TateFeatures etc.

10.5 \strutbox

As p\LaTeX\ (2017/04/08 or later), \strutbox is a macro which is expanded to one of \ystrutbox, \tstrutbox, and \dstrutbox (all of them are shown in Table 15), according to the current direction. Similarly, \strut now uses one of these boxes.

11 Addon packages

Lu\TeX-ja has several addon packages. These addons are written as \LaTeX\ packages, but luatexja-otf and luatexja-adjust can be loaded in plain Lu\TeX\ by \input.

11.1 luatexja-fontspec

As described in Subsection 3.2, this optional package provides the counterparts for several commands defined in the fontspec package (requires fontspec v2.4). In addition to OpenType font features in the original fontspec, the following “font features” specifications are allowed for the commands of Japanese version:

\begin{verbatim}
\CID=(name), JFM=(name), JFM-var=(name)
These 3 keys correspond to cid, jfm and jfmvar keys for \jfont and \tfont respectively. See Subsections 7.1 and 7.4 for details of cid, jfm and jfmvar keys.
\end{verbatim}

The CID key is effective only when with \NoEmbed described below. The same JFM cannot be used in both horizontal Japanese fonts and vertical Japanese fonts, hence the JFM key will be actually used in YokoFeatures and TateFeatures keys.

\begin{verbatim}
\NoEmbed
By specifying this key, one can use “name-only” Japanese font which will not be embedded in the output PDF file. See Subsection 7.4.
\end{verbatim}

\begin{verbatim}
\Kanjiskip=(bool)
\end{verbatim}

\begin{verbatim}
\TateFeatures=(features), TateFont=(font)
The TateFeatures key specifies font features which are only turned on in vertical writing, such as Style=VerticalKana (vkna feature). Similarly, the TateFont key specifies the Japanese font which will be used only in vertical writing. A demonstration is shown in Figure 7.
\end{verbatim}
日本の国民は、正当に選挙された国会における代表者を通じて行動し、われらとわれらの子孫のために、諸国民との協和による成果と、わが国全土にわたって自由のもたらす恵沢を確保し、……

日本国民は、正当に選挙された国会における代表者を通じて行動し、われらとわれらの子孫のために、諸国民との協和による成果と、わが国全土にわたって自由のもたらす恵沢を確保し、……
以上の原理は、「包除原理」とよく呼ばれるが

The value of $\text{kanjiskip}$ is $0\text{ pt} + \frac{1}{5}\text{ em}$ in this figure, for making the difference obvious.

Figure 9. Line adjustment

11.2 luatexja-otf

This optional package supports typesetting glyphs by specifying a CID number. The package luatexja-otf offers the following 2 low-level commands:

\CID{⟨number⟩}

Typeset a glyph whose CID number is $⟨\text{number}⟩$. If the Japanese font is neither Adobe-Japan1, Adobe-GB1, Adobe-CNS1, Adobe-Korea1, nor Adobe-KR CID-keyed font, LuaTeX-ja treats that $⟨\text{number}⟩$ is a CID number of Adobe-Japan1 character collection, and tries to typeset a "most suitable glyph".

Note that if the Japanese font is loaded using the HarfBuzz library, this \CID command does not work.

\UTF{⟨hex_number⟩}

Typeset a character whose character code is $⟨\text{hex_number}⟩$ (in hexadecimal). This command is similar to \char"⟨\text{hex_number}⟩", but please remind remarks below.

This package automatically loads luatexja-ajmacros.sty, which is slightly modified version of ajmacros.sty\footnote{Useful macros by iNOUE Koichi!, for the japanese-otf package.}. Hence one can use macros which are defined in ajmacros.sty, such as \aj半角.

Remarks Characters by \CID and \UTF commands are different from ordinary characters in the following points:

- Always treated as JAchars.
- In vertical direction, \verb/vrt2 feature are automatically applied to characters by \UTF, regardless these feature are not activated in current Japanese font.
- Processes for supporting other OpenType features (for example, glyph replacement and kerning) by the luaotfload package is not performed to these characters.

Additional syntax of JFM The package luatexja-otf extends the syntax of JFM; the entries of \texttt{chars} table in JFM now allows a string in the form 'AJ1-xxx', which stands for the character whose CID number in Adobe-Japan1 is xxx.

This extended notation is used in the standard JFM \texttt{jfm-ujis.lua} to typeset halfwidth Hiragana glyphs (CID 516–598) in halfwidth.

11.3 luatexja-adjust

(see Japanese version of this manual)

11.4 luatexja-ruby

This addon package provides functionality of "ruby" (furigana) annotations using callbacks of LuaTeX-ja. There is no detailed manual of luatexja-ruby.sty in English. (Japanese manual is another PDF file, luatexja-ruby.pdf.)

Group-ruby By default, ruby characters (the second argument of \ruby) are attached to base characters (the first argument), as one object. This type of ruby is called group-ruby.
As the above example, ruby hangover is allowed on the Hiragana before/after its base characters.

**Mono-ruby** To attach ruby characters to each base characters (mono-ruby), one should use \ruby multiple times:

1. 東西線の\ruby{妙}{みょう}典{でん}駅は…… 東西線の妙典駅は……
2. 東西線の\ruby{妙}{みょう}典{でん}駅は…… 東西線の妙典駅は……
3. 東西線の\ruby{妙}{みょう}典{でん}という駅…… 東西線の妙典という駅……
4. 東西線\ruby{葛}{かさい}西駅は…… 東西線の妙典駅は……

**Jukugo-ruby** Vertical bar | denotes a boundary of groups.

1. \ruby{妙}{みょう}典{でん}駅は…… 妙典駅は……
2. \ruby{葛}{かさい}西駅は…… 葛西駅は……
3. \ruby{神楽}{かぐら}坂{さか}駅は…… 神楽坂駅は……

If there are multiple groups in one \ruby call, A linebreak between two groups is allowed.

1. \vbox{hs=6\zw\noindent}……を承うけたまわる
2. \vbox{hs=8\zw\noindent}……を承うけたまわる
3. \null\kern3\zw……を承うけたまわる
4. \null\kern5\zw……を承うけたまわる

If the width of ruby characters are longer than that of base characters, \ruby automatically selects the appropriate form among the line-head form, the line-middle form, and the line-end form.

1. \vbox{hs=6\zw\noindent}京急蒲田
2. \vbox{hs=8\zw\noindent}京急蒲田
3. \null\kern3\zw京急蒲田
4. \null\kern5\zw京急蒲田
5. 

11.5 lltjext.sty

pLaTEX supplies additional macros for vertical writing in the plext package. The ltjext package which we want to describe here is the LuaLaTEX-ja counterpart of the plext package.

**tabular, array, minipage environments**

These environments are extended by <dir>, which specifies the direction, as follows:

\begin{tabular}<dir>[pos]{table spec} ... \end{tabular}
\begin{array}<dir>[pos]{table spec} ... \end{array}
\begin{minipage}<dir>[pos]{width} ... \end{minipage}

This option permits one of the following five values. If none of them is specified, the direction inside the environment is same as that outside the environment.

y yoko direction (horizontal writing)
t tate direction (vertical writing)
z utod direction if direction outside the env. is tate.
d dtou direction
u utod direction

\parbox<\dir>[\pos]{\width}{\contents}
\parbox command is also extended by <<<dir>>.
This commands typeset \texttt{\{contents\}} in LR-mode, in \texttt{\{dir\}} direction. If \texttt{\{width\}} is positive, the width of the box becomes this \texttt{\{width\}}. In this case, \texttt{\{contents\}} will be aligned to left (when \texttt{\{pos\}} is \texttt{l}), center (\texttt{c}), or right (\texttt{r}).

\textbf{picture environment}

picture environment also extended by \texttt{\{dir\}}, as follows:

\begin{picture}\texttt{\{dir\}}(x\_size, y\_size)(x\_offset,y\_offset)
...
\end{picture}

\texttt{\{contents\}}, \texttt{\{counter\_name\}}, \texttt{\{kozuka\_pr6n\}}, \texttt{\{hiragino\_pron\}}, \texttt{\{match\}}, \texttt{\{no\_math\}}, \texttt{\{nfssonly\}}, \texttt{\{setmainfont\}}, \texttt{\{fontspec\}}

egin{verbatim}
\usepackage[no-math]{fontspec}
\usepackage[match]{luatexja-fontspec}
\usepackage[kozuka-pr6n,match]{luatexja-preset}
\end{verbatim}

11.6 \textit{luatexja-preset}

As described in Subsection 3.3, One can load the \texttt{luatexja-preset} package to use several “presets” of Japanese fonts. This package provides functions in a part of \texttt{japanese-otf} package (changing fonts) and a part of \texttt{PXchfon} package (presets) by Takayuki Yato.

Options which are given in \texttt{\usepackage} but not described in this subsection are simply passed to the \texttt{luatexja-fontspec} \textsuperscript{12}. For example, the line 5 in below example is equivalent to lines 1–3.

\begin{verbatim}
\usepackage[no-math]{fontspec}
\usepackage[match]{luatexja-fontspec}
\usepackage[kozuka-pr6n]{luatexja-preset}
\end{verbatim}

\textbf{General Options}

\texttt{fontspec} (enabled by default)

With this option, Japanese fonts are selected using functionality of the \texttt{luatexja-fontspec} package. This means that the \texttt{fontspec} package is automatically loaded by this package.

If you need to pass some options to \texttt{fontspec}, you can load \texttt{fontspec} manually before \texttt{luatexja-preset}:

\begin{verbatim}
\usepackage[no-math]{fontspec}
\usepackage{...}{luatexja-preset}
\end{verbatim}

\texttt{nfssonly}

With this option, selecting Japanese fonts won’t be performed using the functionality of the \texttt{fontspec} package, but only standard NFSS2 (hence without \texttt{\addfontfeatures} etc.). This option is ignored when \texttt{luatexja-fontspec} package is loaded.

When this option is specified, \texttt{fontspec} and \texttt{luatexja-fontspec} are \textit{not} loaded by default. Nevertheless, the \texttt{packagefontspec} can coexist with the option, as the following:

\begin{verbatim}
\usepackage{fontspec}
\usepackage[hiragino-pron,nfssonly]{luatexja-preset}
\end{verbatim}

In this case, one can use \texttt{\setmainfont} etc. to select \textit{alphabetic} fonts.

\textsuperscript{12}if \texttt{nfssonly} option is \textit{not} specified; in this case these options are simply ignored.
match
If this option is specified, usual family-changing commands such as \rmfamily, \textrm, \sffamily, ... also change Japanese font family. This option is passed to luatexja-fontspec, if fontspec option is specified.

nodeluxe (enabled by default)
The negation of deluxe option. Use one-weighted mincho and gothic font families. This means that \mcfamily\bfseries, \gtfamily\bfseries and \gtfamily\mdseries use the same font.

deluxe
Use the mincho family with three weights (light, medium, and bold), the gothic family with three weights (medium, bold, and extra bold), and rounded gothic. Mincho light and gothic extra bold can be by \mcfamily\ltseries and \gtfamily\ebseries, respectively.

• Some presets do not have the light weight of mincho. In this case, we substitute the medium weight for the light weight.
• luatexja-preset does not produce an error (only produces a warning), even if (one of) fonts for \mcfamily\ltseries, \gtfamily\ebseries, \mgfamily do not exist.

expert
Use horizontal/vertical kana alternates, and define a command \rubyfamily to use kana characters designed for ruby.

bold
Substitute bold series of gothic for bold series of mincho. If nodeluxe option is enabled, medium series of gothic is also changed, since we use same font for both series of gothic.

jis90, 90jis
Use JIS X 0208:1990 glyph variants if possible.

jis2004, 2004jis
Use JIS X 0213:2004 glyph variants if possible.

jfm_yoko=(jfm)
Use the JFM jfm-(jfm).lua for horizontal direction, instead of jfm-ujis.1ua (default JFM).

jfm_tate=(jfm)
Use the JFM jfm-(jfm).lua for vertical direction, instead of jfm-ujisv.1ua (default JFM).

jis
Same as jfm_yoko=jis.

Note that jis90, 90jis, jis2004 and 2004jis only affect with mincho, gothic (and, possibly rounded gothic) families defined by this package. We didn’t taken account of when more than one options among them are specified.

11.6.2 Presets which support multi weights
Besides bizud, haranoaji, morisawa-pro, and morisawa-pr6n presets, fonts are specified by font name, not by file name. In following tables, starred fonts (e.g. KozGo...-Regular) are used for medium series of gothic, if and only if deluxe option is specified.

kozuka-pro Kozuka Pro (Adobe-Japan1-4) fonts.
kozuka-pr6 Kozuka Pr6 (Adobe-Japan1-6) fonts.
kozuka-pr6n Kozuka Pr6N (Adobe-Japan1-6, JIS04-savvy) fonts.

Kozuka Pro/Pr6N fonts are bundled with Adobe’s software, such as Adobe InDesign. There is not rounded gothic family in Kozuka fonts.

Provided by \mgfamily and \textmg, because “rounded gothic” is called maru gothic (丸ゴシック) in Japanese.

11.6.3 Presets which do not support multi weights

Next, we describe settings for using only single weight.

<table>
<thead>
<tr>
<th>noembed</th>
<th>ipa</th>
<th>ipax</th>
<th>ms</th>
</tr>
</thead>
<tbody>
<tr>
<td>mincho</td>
<td>Ryumin-Light (non-embedded)</td>
<td>IPA Mincho</td>
<td>IPAex Mincho</td>
</tr>
<tr>
<td>gothic</td>
<td>GothicBBB-Medium (non-embedded)</td>
<td>IPA Gothic</td>
<td>IPAex Gothic</td>
</tr>
</tbody>
</table>
11.6.4 Presets which use HG fonts

We can use HG fonts bundled with Microsoft Office for realizing multiple weights. In the table below, starred fonts (e.g., IPA Gothic*) are used only if jis2004 or nodeluxe option is specified.

<table>
<thead>
<tr>
<th>family</th>
<th>series</th>
<th>ipa-hg</th>
<th>ipaes-hg</th>
<th>ns-hg</th>
</tr>
</thead>
<tbody>
<tr>
<td>mincho</td>
<td>medium</td>
<td>IPA Mincho</td>

<td>HG Soei Kaku Gothic UB</td>
<td></td>
</tr>
<tr>
<td>rounded gothic</td>
<td></td>
<td>HG Maru Gothic M PRO</td>
<td>HG Maru Gothic M PRO</td>
<td></td>
</tr>
</tbody>
</table>

Note that HG Mincho E, HG Gothic E, HG Soei Kaku Gothic UB, and HG Maru Gothic PRO are internally specified by:

\textbf{default} by font name (\texttt{HGMinchoE}, etc.).
\textbf{jis90, 90jis} by file name (\texttt{hgrme.ttc}, \texttt{hgrge.ttc}, \texttt{hgrsgu.ttc}, \texttt{hgrsmp.ttf}).
\textbf{jis2004, 2004jis} by file name (\texttt{hgrme04.ttc}, \texttt{hgrge04.ttc}, \texttt{hgrsgu04.ttc}, \texttt{hgrsmp04.ttf}).

11.6.5 Define/Use Custom Presets

From version 20170904.0, one can define new presets using \texttt{\ltjnewpreset}, and use them by \texttt{\ltjapplypreset}. These two commands can only be used in the preamble.

\texttt{\ltjnewpreset\{name\}\{specification\}}

Define new preset \textit{(name)}. This \textit{(name)} cannot be same as other presets, options described in Subsubsection 11.6.1, nor following 11 strings:

\texttt{mc mc-l mc-m mc-b mc-bx gt gt-m gt-b gt-bx gt-eb mg-m}

\textit{(specification)} is a comma-separated list which consists of other presets and/or the following keys:

\texttt{mc-l=\{font\} mincho light}
\texttt{mc-m=\{font\} mincho medium}
\texttt{mc-b=\{font\} mincho bold}
\texttt{mc-bx=\{font\} synonym for mc-b=\{font\}}
\texttt{gt-m=\{font\} gothic medium}
\texttt{gt-b=\{font\} gothic bold}
\texttt{gt-bx=\{font\} synonym for gt-b=\{font\}}
\texttt{gt-eb=\{font\} gothic extra bold}
\texttt{mg-m=\{font\} rounded gothic}
\texttt{mc=\{font\} Same as}

\texttt{mc-l=\{font\}, mc-m=\{font\}, mc-b=\{font\}}
\texttt{gt=\{font\} Same as}

\texttt{gt-m=\{font\}, gt-b=\{font\}, gt-eb=\{font\}}

If \texttt{deluxe} is not specified at loading the package, only \texttt{mc} and \texttt{gt} keys (among above 11 keys) have a meaning.

\texttt{\ltjnewpreset*\{name\}\{specification\}}

Almost same as \texttt{\ltjnewpreset}. However, if \textit{(name)} matches a preset which already defined, this command simply overwrite it.
\texttt{\textbackslash ltjapplypreset\{\textit{name}\}}

Set Japanese font families using preset \textit{name}.

Note that \texttt{\textbackslash ltjnewpreset} does not "expand" the definition to define a preset. This means that one can write as the following:

\begin{verbatim}
\texttt{\textbackslash ltjnewpreset\{hoge\}\{piyo,mc-b=HiraMinProN-W6\}}
\texttt{\textbackslash ltjnewpreset\{piyo\}\{mg-m=HiraMaruProN-W4\}}
\texttt{\textbackslash ltjapplypreset\{hoge\}}
\end{verbatim}

\section*{Restrictions}

Presets which are defined by \texttt{\textbackslash ltjnewpreset} have following restrictions:

\begin{itemize}
  \item One cannot specify non-embedded fonts (such as Ryumin-Light).
  \item Some presets, such as \texttt{ipa-hg}, have a feature that fonts are changed according to whether \texttt{90jis} or \texttt{jis2004} is specified. This feature is not usable in presets which are defined by \texttt{\textbackslash ltjnewpreset}.
\end{itemize}
Part III
Implementations

12 Storing Parameters

12.1 Used dimensions, attributes and whatsit nodes

Here the following is the list of dimensions and attributes which are used in Lua\TeX-ja.

\textbackslash jQ (dimension) \textit{\textbackslash jQ} is equal to \textit{1 Q = 0.25 mm}, where "Q" (also called "級") is a unit used in Japanese phototypesetting. So one should not change the value of this dimension.

\textbackslash jH (dimension) There is also a unit called "歯" which equals to 0.25 mm and used in Japanese phototypesetting. This \textit{\textbackslash jH} is the same \texttt{dimen} register as \textit{\textbackslash jQ}.

\texttt{ltj@dimen@zu} (dimension) A temporal register for the "full-width" of current Japanese font. The command \texttt{\zh} sets this register to the correct value, and "return" this register itself.

\texttt{ltj@dimen@zh} (dimension) A temporal register for the "full-height" (usually the sum of height of imaginary body and its depth) of current Japanese font. The command \texttt{\zh} sets this register to the correct value, and "return" this register itself.

\texttt{\jfam} (attribute) Current number of Japanese font family for math formulas.

\texttt{\ltj@curjfnt} (attribute) If this attribute is a positive number, it stores the font number of current Japanese font for horizontal direction. If this attribute is negative, it means that the Japanese font for horizontal direction is not loaded—Lua\TeX-ja only knows its size and JFM.

\texttt{\ltj@curtfnt} (attribute) Similar to \texttt{\ltj@curjfnt}, but with current Japanese font for vertical direction.

\texttt{\ltj@charclass} (attribute) The character class of a \texttt{JAchar}. This attribute is only set on a \texttt{glyph_node} which contains a \texttt{JAchar}.

\texttt{\ltj@yablshift} (attribute) The amount of shifting the baseline of alphabetic fonts in scaled point \texttt{(2^{16} pt)}.

\texttt{\ltj@yblshift} (attribute) The amount of shifting the baseline of Japanese fonts in scaled point \texttt{(2^{16} pt)}.

\texttt{\ltj@tablshift} (attribute)

\texttt{\ltj@tkblshift} (attribute)

\texttt{\ltj@autospc} (attribute) Whether the auto insertion of \texttt{kanjiskip} is allowed at the node.

\texttt{\ltj@autoxspc} (attribute) Whether the auto insertion of \texttt{xkanjiskip} is allowed at the node.

\texttt{\ltj@icflag} (attribute) An attribute for distinguishing "kinds" of a node. One of the following value is assigned to this attribute:

\textit{italic} \textcircled{1} Kerns from italic correction (\textbackslash /), or from kerning information of a Japanese font. These kerns are "ignored" in the insertion process of \texttt{JAglue}, unlike explicit \textbackslash kern.

\textit{packed} \textcircled{2} Kerns from \texttt{kanjiskip}.

\textit{kinsoku} \textcircled{3} Penalties inserted for the word-wrapping process (kinsoku shori) of Japanese characters.

\textit{from_jfm}–(\textit{from_jfm} + 63) \textit{(4–67)} Glues/kerns from JFM.

\textit{kanji_skip} \texttt{(68)}, \textit{kanji_skip_jfm} \texttt{(69)} Glues from \texttt{kanjiskip}.

\textit{xkanji_skip} \texttt{(70)}, \textit{xkanji_skip_jfm} \texttt{(71)} Glues from \texttt{xkanjiskip}.

\textit{processed} \texttt{(73)} Nodes which is already processed by ....
ic_processed (74) Glues from an italic correction, but already processed in the insertion process of JAgles.

boxbd (75) Glues/kerns that inserted just the beginning or the ending of an hbox or a paragraph.

\ltj@kcat i (attribute) Where i is a natural number which is less than 7. These 7 attributes store bit vectors indicating which character block is regarded as a block of JChar.

\ltj@dir (attribute) dir_node_auto (128)

dir_node_manual (256)

Furthermore, LuaTEX-ja uses several user-defined whatsit nodes for internal processing. All those nodes except direction whatsis store a natural number (hence its type is 100). direction whatsis store a node list, hence its type is 110. Their user_id (used for distinguish user-defined whatsis) are allocated by luatexbase.newuserwhatsitid.

inhibitglue Nodes for indicating that \inhibitglue is specified. The value field of these nodes doesn’t matter.

stack_marker Nodes for LuaTEX-ja’s stack system (see the next subsection). The value field of these nodes is current group level.

char_by_cid Nodes for JChar which processes by luaotfload won’t be applied, and the character code is stored in the value field. Each node of this type are converted to a glyph_node after processes by luaotfload. Nodes of this type is used in \CID and \UTF.

replace_vs Similar to char_by_cid whatsis above. These nodes are for ALChar which the callback process of luaotfload won’t be applied.

begin_par Nodes for indicating beginning of a paragraph. A paragraph which is started by \item in list-like environments has a horizontal box for its label before the actual contents. So ...

direction

These whatsis will be removed during the process of inserting JAgles.

12.2 Stack system of LuaTEX-ja

■ Background LuaTEX-ja has its own stack system, and most parameters of LuaTEX-ja are stored in it. To clarify the reason, imagine the parameter kanjiskip is stored by a skip, and consider the following source:

1 \ltjsetparameter{kanjiskip=0pt}ふがふが。
2 \setbox0=\hbox{%
3 \ltjsetparameter{kanjiskip=5pt}ほげほげ}
4 \box0.ぴよぴよ\par

As described in Subsection 8.1, the only effective value of kanjiskip in an hbox is the latest value, so the value of kanjiskip which applied in the entire hbox should be 5 pt. However, by the implementation method of LuaTEX, this “5 pt” cannot be known from any callbacks. In the tex/packaging.w, which is a file in the source of LuaTEX, there are the following codes:

```c
void package(int c)
{
  scaled h; /* height of box */
  halfword p; /* first node in a box */
  scaled d; /* max depth */
  int grp;
  grp = cur_group;
  d = box_max_depth;
  unsave();
}"
```
\begin{verbatim}
    save_ptr -= 4;
    if (cur_list.mode_field == -hmode) {
        cur_box = filtered_hpack(cur_list.head_field, cur_list.tail_field, saved_value(1), saved_level(1), grp, saved_level(2));
        subtype(cur_box) = HLIST_SUBTYPE_HBOX;
    }
\end{verbatim}

Notice that \texttt{unsave()} is executed before \texttt{filtered_hpack()}, where \texttt{hpack_filter} callback is executed here. So "5 pt" in the above source is orphaned at \texttt{unsave()}, and hence it can’t be accessed from \texttt{hpack_filter} callback.

\section*{Implementation}
The code of stack system is based on that in a post of Dev-luatex mailing list\textsuperscript{14}.

These are two \TeX\ count registers for maintaining information: `\texttt{\@stack}` for the stack level, and `\texttt{\@group@level}` for the \TeX\’s group level when the last assignment was done. Parameters are stored in one big table named \texttt{charprop_stack_table}, where \texttt{charprop_stack_table[i]} stores data of stack level \texttt{i}. If a new stack level is created by `\texttt{\@setparameter}`, all data of the previous level is copied.

To resolve the problem mentioned in above paragraph “Background”, Lua\TeX-ja uses another trick. When the stack level is about to be increased, a whatsis node whose type, subtype and value are \texttt{44 (user_defined)}, \texttt{stack_marker} and the current group level respectively is appended to the current list (we refer this node by \texttt{stack_flag}). This enables us to know whether assignment is done just inside a hbox. Suppose that the stack level is \( s \) and the \TeX\’s group level is \( t \) just after the hbox group, then:

- If there is no \texttt{stack_flag} node in the list of the contents of the hbox, then no assignment was occurred inside the hbox. Hence values of parameters at the end of the hbox are stored in the stack level \( s \).
- If there is a \texttt{stack_flag} node whose value is \( t + 1 \), then an assignment was occurred just inside the hbox group. Hence values of parameters at the end of the hbox are stored in the stack level \( s + 1 \).
- If there are \texttt{stack_flag} nodes but all of their values are more than \( t + 1 \), then an assignment was occurred in the box, but it is done in more internal group. Hence values of parameters at the end of the hbox are stored in the stack level \( s \).

Note that to work this trick correctly, assignments to `\texttt{\@stack}` and `\texttt{\@group@level}` have to be local always, regardless the value of `\texttt{\globaldefs}`. To solve this problem, we use another trick: the assignment `\texttt{\directlua{tex.globaldefs=0}}` is always local.

\subsection*{12.3 Lua functions of the stack system}
In this subsection, we will see how a user use Lua\TeX-ja’s stack system to store some data which obeys the grouping of \TeX.

The following function can be used to store data into a stack:
\begin{verbatim}
luatexja.stack.set_stack_table(index, <any> data)
\end{verbatim}

Any values which except \texttt{nil} and \texttt{NaN} are usable as \texttt{index}. However, a user should use only negative integers or strings as \texttt{index}, since natural numbers are used by Lua\TeX-ja itself. Also, whether \texttt{data} is stored locally or globally is determined by \texttt{luatexja.isglobal} (stored globally if and only if \texttt{luatexja.isglobal = 'global'}).

Stored data can be obtained as the return value of
\begin{verbatim}
luatexja.stack.get_stack_table(index, <any> default, <number> level)
\end{verbatim}

where \texttt{level} is the stack level, which is usually the value of \texttt{\@stack}, and \texttt{default} is the default value which will be returned if no values are stored in the stack table whose level is \texttt{level}.

\subsection*{12.4 Extending Parameters}
Keys for `\texttt{\@setparameter}` and `\texttt{\@getparameter}` can be extended, as in \texttt{luatexja-adjust}.

\textsuperscript{14}[Dev-luatex] \texttt{tex.currentgrouplevel}, a post at 2008/8/19 by Jonathan Sauer.
\protected\def\ltj@setpar@global{% 
\relax\ifnum\globaldefs>0\directlua{luatexja.isglobal='global'}% 
\else\directlua{luatexja.isglobal=''}\fi 
}% 
\protected\def\ltjsetparameter#1{\ltj@setpar@global\setkeys[ltj]{japaram}{#1}\ignorespaces}% 
\protected\def\ltjglobalsetparameter#1{\relax\ifnum\globaldefs<0\directlua{luatexja.isglobal=''}% 
\else\directlua{luatexja.isglobal='global'}\fi\setkeys[ltj]{japaram}{#1}\ignorespaces}%

Figure 10. Definition of parameter setting commands

\textbf{Setting parameters} Figure 10 shows the most outer definition of two commands, \texttt{\ltjsetparameter} and \texttt{\ltjglobalsetparameter}. Most important part is the last \texttt{\setkeys}, which is offered by the \texttt{xkeyval} package.

Hence, to add a key in \texttt{\ltjsetparameter}, one only have to add a key whose prefix is \texttt{ltj} and whose family is \texttt{japaram}, as the following.
\texttt{\define@key[ltj]{japaram}{...}{...}}
\texttt{\ltjsetparameter} and \texttt{\ltjglobalsetparameter} automatically sets \texttt{luatexja.isglobal}. Its meaning is the following.

\begin{equation}
\texttt{luatexja.isglobal} = \begin{cases} 'global' & (\text{global assignment}), \\ \text{'} & (\text{local assignment}). \end{cases}
\end{equation}

This is determined not only by command name (\texttt{\ltjsetparameter} or \texttt{\ltjglobalsetparameter}), but also by the value of \texttt{\globaldefs}.

\textbf{Getting parameters} \texttt{\ltjgetparameter} is implemented by a Lua script.

For parameters that do not need additional arguments, one only have to define a function in the table \texttt{luatexja.unary_pars}. For example, with the following function, \texttt{\ltjgetparameter{hoge}} returns a string 42.
\begin{verbatim}
function luatexja.unary_pars.hoge (t)
    return 42
end
\end{verbatim}

Here the argument of \texttt{luatexja.unary_pars.hoge} is the stack level of Lua\TeX-ja’s stack system (see Subsection 12.2).

On the other hand, for parameters that need an additional argument (this must be an integer), one have to define a function in \texttt{luatexja.binary_pars} first. For example,
\begin{verbatim}
function luatexja.binary_pars.fuga (c, t)
    return tostring(c) .. ', ' .. tostring(42)
end
\end{verbatim}

Here the first argument \texttt{t} is the stack level, as before. The second argument \texttt{c} is just the second argument of \texttt{\ltjgetparameter}.

For parameters that need an additional argument, one also have to execute the \TeX code like \texttt{\ltj@@decl@array@param{fuga}} to indicate that “the parameter fuga needs an additional argument”.

13 Linebreak after a Japanese Character

13.1 Reference: behavior in \texttt{p\TeX}

In \texttt{p\TeX}, a line break after a Japanese character doesn’t emit a space, since words are not separated by spaces in Japanese writings. However, this feature isn’t fully implemented in Lua\TeX-ja due to the specification of
We omitted about category codes 9 (ignored), 14 (comment), and 15 (invalid) from the above diagram. We also ignored the input like "^^A" or "^^df".

When a character whose category code is 0 (escape character) is seen by \TeX, the input processor scans a control sequence (scan a c.s.). These paths are not shown in the above diagram. After that, the state is changed to State \( S \) (skipping blanks) in most cases, but to State \( M \) (middle of line) sometimes.

Figure 11. State transitions of \pTeX's input processor

callbacks in \LuaTeX. To clarify the difference between \pTeX and \LuaTeX, We briefly describe the handling of a line break in \pTeX, in this subsection.

\pTeX's input processor can be described in terms of a finite state automaton, as that of \TeX in Section 2.5 of [1]. The internal states are as follows:

- State \( N \): new line
- State \( S \): skipping spaces
- State \( M \): middle of line
- State \( K \): after a Japanese character

The first three states—\( N, S, \) and \( M \)—are as same as \TeX's input processor. State \( K \) is similar to state \( M \), and is entered after Japanese characters. The diagram of state transitions are indicated in Figure 11. Note that \pTeX doesn’t leave state \( K \) after “beginning/ending of a group” characters.

### 13.2 Behavior in \LuaTeX-ja

States in the input processor of \LuaTeX is the same as that of \TeX, and they can’t be customized by any callbacks. Hence, we can only use process_input_buffer and token_filter callbacks for to suppress a space by a line break which is after Japanese characters.

However, token_filter callback cannot be used either, since a character in category code 5 (end-of-line) is converted into an space token in the input processor. So we can use only the process_input_buffer callback. This means that suppressing a space must be done just before an input line is read.

Considering these situations, handling of an end-of-line in \LuaTeX-ja are as follows:

A character whose character code is \texttt{\textbackslash l}tjl\texttt{\textbackslash lineendcomment} is appended to an input line, before \LuaTeX actually process it, if and only if the following three conditions are satisfied:

1. The category code of \texttt{\textbackslash endlinechar} is 5 (end-of-line).
2. The category code of \texttt{\textbackslash l}tjl\texttt{\textbackslash lineendcomment} itself is 14 (comment).

\footnote{\texttt{\textbackslash endlinechar} usually, it is \texttt{(return)} (whose character code is 13).}
3. The input line matches the following "regular expression":

\[(any \text{char})(\text{JAchar})(\text{catcode = 1} \cup \text{catcode = 2})]^{*}\]

**Remark** The following example shows the major difference from the behavior of \TeX{}.

```latex
\fontspec[Ligatures=TeX]{Linux Libertine O}
\ltjsetparameter{autoxspacing=false}
\ltjsetparameter{jacharrange={-6}}
\quad \text{あ}
\quad \text{い}
\quad \text{う}
\quad \text{ゆ} \quad \text{い} \quad \text{う}
```

It is not strange that "あ" does not printed in the above output. This is because \TeX{} Gyre Termes does not contain "あ", and because "あ" in line 3 is considered as an ALchar.

Note that there is no space before "y" in the output, but there is a space before "u". This follows from following reasons:

- When line 3 is processed by `process_input_buffer` callback, "あ" is considered as a JAchar. Since line 3 ends with a JAchar, the comment character (whose character code is `\ltjlineendcomment`) is appended to this line, and hence the linebreak immediately after this line is ignored.
- When line 4 is processed by `process_input_buffer` callback, "い" is considered as an ALchar. Since line 4 ends with an ALchar, the linebreak immediately after this line emits a space.

## 14 Patch for the listings Package

It is well-known that the listings package outputs weird results for Japanese input. The listings package makes most of letters active and assigns output command for each letter ([2]). But Japanese characters are not included in these activated letters. For \TeX{} series, there is no method to make Japanese characters active; a patch `jlisting.sty` ([4]) resolves the problem forcibly.

In Lua\TeX{}-ja, the problem is resolved by using the processInputBuffer callback. The callback function inserts the output command (active character `\ltjlineendcomment`) before each letter above \text{U+0080}. This method can omits the process to make all Japanese characters active (most of the activated characters are not used in many cases).

If the listings package and Lua\TeX{}-ja were loaded, then the patch ltjtp-listings is loaded automatically at \texttt{\begin{document}}.

### 14.1 Notes and additional keys

**Variation selectors** `ltjtp-listings` add two keys, namely `vsraw` and `vscmd`, which specify how variation selectors are treated in `\lstlisting` or other environments. Note that these additional keys are not usable in the preamble, since `ltjtp-listings` is loaded at \texttt{\begin{document}}.

`\begin{lstlisting}[\texttt{vsraw=true}]`

葛城市,葛飾区,葛西

`\end{lstlisting}`

- If the `\texttt{vsraw}` key is true, then variation selectors are "combined" with the previous character.

`\begin{lstlisting}[\texttt{vsraw=false, vscmd=\ltjlistingsvsstdcmd}]`

葛城市,葛飾区,葛西

`\end{lstlisting}`

- If the `\texttt{vsraw}` key is false, then variation selectors are typeset by an appropriate command, which is specified by the `\texttt{vscmd}` key. The default setting of the `\texttt{vscmd}` key produces the following.
For example, the following code is the setting of the \vscmd key in this document.

\def\IVSA#1#2#3#4#5{% 
\hbox to1em{\hss\textcolor{blue}{\raisebox{3.5pt}{\normalfont\ttfamily% 
\fboxsep=0.5pt\fbox{\hbox to0.75em{\hss\tiny \oalign{0#1#2\crcr#3#4#5\crcr}\hss}}}}\hss} \%
\}
\{\catcode\%=11
\gdef\IVSB#1{\expandafter\IVSA\directlua{
local cat_str = luatexbase.catcodetables['string']
tex.sprint(cat_str, string.format('%X', 0xE00EF+#1))\}}}}\lstset{vscmd=\IVSB}

The default output command of variation selectors is stored in \ltjlistingsvsstdcmd.

\begin{itemize}
\item The \texttt{doubleletterspace} key
\end{itemize}

Even the column format is \texttt{[c]} fixed, sometimes characters are not vertically aligned. The following example is typeset with \texttt{basewidth=2em}, and you’ll see the leftmost “H” are not vertically aligned.

\begin{verbatim}
  \lstinline{  H :  }  \H H H H :
\end{verbatim}

\texttt{lltjp-listing} adds the \texttt{doubleletterspace} key (not activated by default, for compatibility) to improve the situation, namely doubles inter-character space in each output unit. With this key, the above input now produces better output.

\begin{verbatim}
  \lstinline{  H :  }  \H H H H :
\end{verbatim}

\subsection{Class of characters}

Roughly speaking, the \texttt{listings} package processes input as follows:

1. Collects \texttt{letters} and \texttt{digits}, which can be used for the name of identifiers.

2. When reading an \texttt{other}, outputs the collected character string (with modification, if needed).

3. Collects \texttt{others}.

4. When reading a \texttt{letter} or a \texttt{digit}, outputs the collected character string.

5. Turns back to 1.

By the above process, line breaks inside of an identifier are blocked. A flag \texttt{\lst@ifletter} indicates whether the previous character can be used for the name of identifiers or not.

For Japanese characters, line breaks are permitted on both sides except for brackets, dashes, etc. Hence the patch \texttt{lltjp-listings} introduces a new flag \texttt{\lst@ifkanji}, which indicates whether the previous character is a Japanese character or not. For illustration, we introduce following classes of characters:

\begin{center}
\begin{tabular}{ l l l }
\hline
Letter & Other & Meaning \\
\hline
\texttt{\lst@ifletter} & T & char in an identifier \\
\texttt{\lst@ifkanji} & F & other alphabet \\
\texttt{Meaning} & & char in an identifier other alphabet \\
\hline
\end{tabular}
\begin{tabular}{ l l l }
\hline
Kanji & Open & Close \\
\hline
\texttt{\lst@ifletter} & T & F & T \\
\texttt{\lst@ifkanji} & T & F & T \\
\texttt{Meaning} & most of Japanese char & opening brackets & closing brackets \\
\hline
\end{tabular}
\end{center}
Note that digits in the listings package can be Letter or Other according to circumstances.

For example, let us consider the case an Open comes after a Letter. Since an Open represents Japanese open brackets, it is preferred to be permitted to insert line break after the Letter. Therefore, the collected character string is output in this case.

The following table summarizes $5 \times 5 = 25$ cases:

<table>
<thead>
<tr>
<th>Prev</th>
<th>Next</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In the above table,

- “outputs” means to output the collected character string (i.e., line breaking is permitted there).
- “collects” means to append the next character to the collected character string (i.e., line breaking is prohibited there).

Characters above or equal to U+0080 except Variation Selectors are classified into above 5 classes by the following rules:

- **ALchars** above or equal to U+0080 are classified as Letter.
- **JAchars** are classified in the order as follows:
  1. Characters whose `prebreakpenalty` is greater than or equal to 0 are classified as Open.
  2. Characters whose `postbreakpenalty` is greater than or equal to 0 are classified as Close.
  3. Characters that don’t satisfy the above two conditions are classified as Kanji.

The width of halfwidth kana (U+FF61–U+FF9F) is same as the width of ALchar; the width of the other JAchars is double the width of ALchar.

This classification process is executed every time a character appears in the lstlisting environment or other environments/commands.

## 15 Cache Management of LuaTeX-ja

LuaTeX-ja creates some cache files to reduce the loading time, in a similar way to the luaotfload package:

- Cache files are usually stored in (and loaded from) `$TEXMFVAR/luatexja/`.
- In addition to caches of the text form (the extension is `.lua`), caches of the binary, precompiled form are supported.
  - In loading a cache, the binary cache precedes the text form.
  - When LuaTeX-ja updates a cache *hoge.lua*, its binary version is also updated.

### 15.1 Use of cache

LuaTeX-ja uses the following cache:

**ltj-cid-auto-adobe-japan1.lua**

The font table of a CID-keyed non-embedded Japanese font. This is loaded in every run. It is created from three CMaps, UniJIS2004-UTF32-{H,V} and Adobe-Japan1-UCS2, and this is why these two CMaps are needed in the first run of LuaTeX-ja.

Similar caches are created as Table 16, if you specified `cid` key in `\jfont` to use other CID-keyed non-embedded fonts for Chinese or Korean, as in Page 25.
Table 16. cid key and corresponding files

<table>
<thead>
<tr>
<th>cid key</th>
<th>name of the cache</th>
<th>used CMaps</th>
</tr>
</thead>
<tbody>
<tr>
<td>Adobe-Japan1-*</td>
<td>ltj-cid-auto-adobe-japan1.lua</td>
<td>UniJIS2004-UTF32-* Adobe-Japan1-UCS2</td>
</tr>
<tr>
<td>Adobe-Korea1-*</td>
<td>ltj-cid-auto-adobe-korea1.lua</td>
<td>UniKS-UTF32-* Adobe-Korea1-UCS2</td>
</tr>
<tr>
<td>Adobe-GB1-*</td>
<td>ltj-cid-auto-adobe-gb1.lua</td>
<td>UniGB-UTF32-* Adobe-GB1-UCS2</td>
</tr>
<tr>
<td>Adobe-CNS1-*</td>
<td>ltj-cid-auto-adobe-cns1.lua</td>
<td>UniCNS-UTF32-* Adobe-CNS1-UCS2</td>
</tr>
</tbody>
</table>

ltj-jisx0208.{luc|lub}

The bytecode version of ltj-jisx0208.lua. This is the conversion table between JIS X 0208 and Unicode which is used in Kanji-code conversion commands for compatibility with p\TeX.

15.2 Internal

Cache management system of LuaTeX-ja is stored in luatexja.base (ltj-base.lua). There are three public functions for cache management in luatexja.base, where ⟨filename⟩ stands for the file name without suffix:

**save_cache**((filename), (data))

Save a non-nil table (data) into a cache (filename). Both the text form (filename).lua and its binary version are created or updated.

**save_cache_luc**((filename), (data)[, (serialized_data)])

Same as save_cache, except that only the binary cache is updated. The third argument (serialized_data) is not usually given. But if this is given, it is treated as a string representation of (data).

**load_cache**((filename), (outdate))

Load the cache (filename). (outdate) is a function which takes one argument (the contents of the cache), and its return value is whether the cache is outdated.

load_cache first tries to read the binary cache (filename).{luc|lub}. If its contents is up-to-date, load_cache returns the contents. If the binary cache is not found or its contents is outdated, load_cache tries to read the text form (filename).lua. Hence, the return value of load_cache is non-nil, if and only if the updated cache is found.
